Programmable Radio-on-Chip LPstar

Features

- Radio System-on-Chip, with built-in 8-bit MCU in a single device.

- Operates in the unlicensed worldwide Industrial, Scientific, and Medical (ISM) band (2.400 GHz to 2.483 GHz).

- On Air compatible with second generation radio WirelessUSB™ LP and PRoC LP.

- Pin-to-pin compatible with PRoC LP except the Pin31 and Pin37.

Intelligent

- M8C based 8-bit CPU, optimized for human interface devices (HID) applications

- 256 bytes of SRAM

- 8 Kbytes of flash memory with EEPROM emulation

- In-System reprogrammable through D+/D− pins

- CPU speed up to 12 MHz

- 16-bit free running timer

- Low power wakeup timer

- 12-bit programmable interval timer with interrupts

- Watchdog timer

Low Power

- 21 mA operating current (Transmit at –5 dBm)

- Sleep current less than 1 μA

- Operating voltage from 4.0 V to 5.25 V DC

- Fast startup and fast channel changes

- Supports coin-cell operated applications

Reliable and Robust

- Receive sensitivity typical –90 dBm

- AutoRate™ – dynamic data rate reception
  - Enables data reception for any of the supported bit rates automatically.
  - DSSS (250 Kbps), GFSK (1 Mbps)

- Operating temperature from 0 °C to 70 °C

- Closed-loop frequency synthesis for minimal frequency drift

Simple Development

- Auto transaction sequencer (ATS): MCU can stay sleeping longer to save power

- Framing, length, CRC16, and Auto ACK

- Separate 16 byte transmit and receive FIFOs

- Receive signal strength indication (RSSI)

- Built-in serial peripheral interface (SPI) control while in sleep mode

- Advanced development tools based on Cypress's PSoC® Tools

- Flexible I/O

- 2 mA source current on all GPIO pins. Configurable 8 mA or 50 mA/pin current sink on designated pins

- Each GPIO pin supports high impedance inputs, configurable pull-up, open-drain output, CMOS/TTL inputs, and CMOS output

- Maskable interrupts on all I/O pins

BOM Savings

- Low external component count

- Small footprint 40-pin QFN (6 mm × 6 mm)

- GPIOs that require no external components

- Operates off a single crystal

- Integrated 3.3 V regulator

- Integrated pull-up on D-

USB Specification Compliance

- Conforms to USB specification version 2.0

- Conforms to USB HID specification version 1.1

- Supports one low speed USB device address

- Supports one control endpoint and two data end points

- Integrated USB transceiver

Applications

- Wireless keyboards and mice

- Presentation tools

- Wireless gamepads

- Remote controls

- Toys

- Fitness

Logic Block Diagram
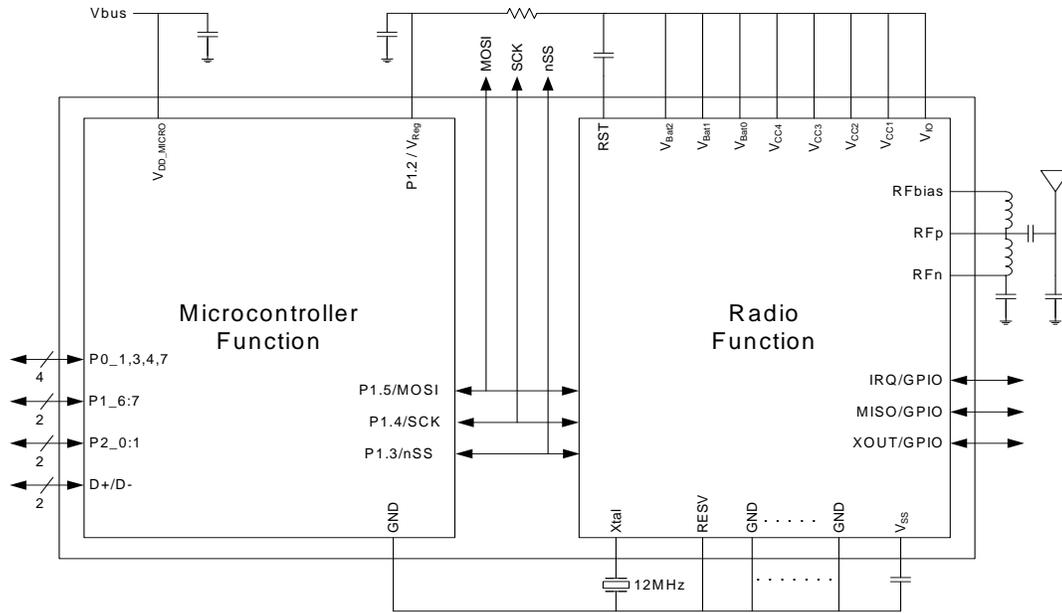

Contents

Functional Description

PRoC LPstar devices are integrated radio and microcontroller functions in the same package to provide a dual role single-chip solution.

Communication between the microcontroller and the radio is via the SPI interface between both functions.

Functional Overview

The CYRF69313 is a complete Radio System-on-Chip device, providing a complete RF system solution with a single device and a few discrete components. The CYRF69313 is designed to implement low cost wireless systems operating in the worldwide 2.4 GHz Industrial, Scientific, and Medical (ISM) frequency band (2.400 GHz–2.4835 GHz).

2.4 GHz Radio Function

The SoC contains a 2.4 GHz, 1 Mbps GFSK radio transceiver, packet data buffering, packet framer, DSSS baseband controller, Received Signal Strength Indication (RSSI), and SPI interface for data transfer and device configuration.

The radio supports 98 discrete 1 MHz channels (regulations may limit the use of some of these channels in certain jurisdictions).

The baseband performs DSSS spreading/despreading, Start of Packet (SOP), End of Packet (EOP) detection, and CRC16 generation and checking. The baseband may also be configured to automatically transmit Acknowledge (ACK) handshake packets whenever a valid packet is received.

When in receive mode, with packet framing enabled, the device is always ready to receive data transmitted at any of the supported bit rates. This enables the implementation of mixed-rate systems in which different devices use different data

rates. This also enables the implementation of dynamic data rate systems that use high data rates at shorter distances or in a low-moderate interference environment or both. It changes to lower data rates at longer distances or in high interference environments or both.

USB Microcontroller Function

The microcontroller function is based on the powerful CYRF69313 microcontroller. It is an 8-bit Flash programmable microcontroller with integrated low speed USB interface.

The microcontroller has up to 14 GPIO pins to support USB, PS/2 and other applications. Each GPIO port supports high impedance inputs, configurable pull-up, open drain output, CMOS/TTL inputs and CMOS output. Up to two pins support programmable drive strength of up to 50 mA. Additionally each I/O pin can be used to generate a GPIO interrupt to the micro-controller. Each GPIO port has its own GPIO interrupt vector with the exception of GPIO Port 0.

The microcontroller features an internal oscillator. With the presence of USB traffic, the internal oscillator can be set to precisely tune to USB timing requirements (24 MHz ± 1.5%).

The PRoC LPstar has up to 8 Kbytes of Flash for user's firmware code and up to 256 bytes of RAM for stack space and user variables.

Backward Compatibility

The CYRF69313 IC is fully interoperable with the main modes of the second generation Cypress radio SoC namely the CYRF6936, CYRF69103 and CYRF69213.

CYRF69313 IC device may transmit data to or receive data from a second generation device, or both.

Pinouts

Figure 1. 40-Pin QFN
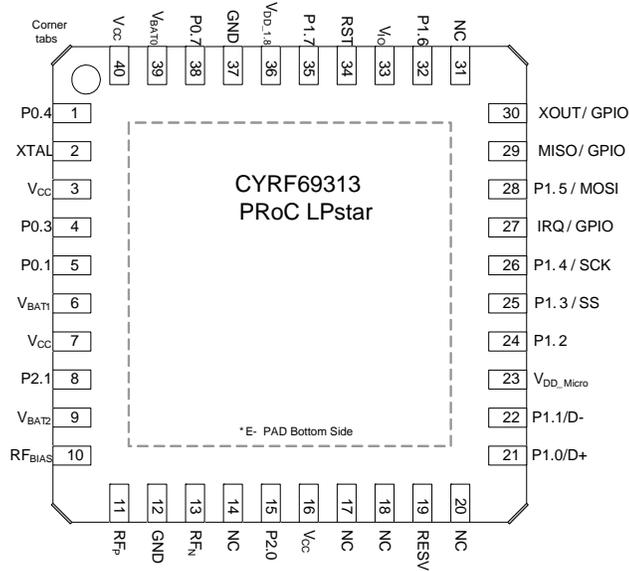

Pin Configuration

Pin	Name	Function
1	P0.4	Individually configured GPIO
2	Xtal_in	12 MHz Crystal. External clock in
3, 7, 16, 40	V_{CC}	Connected to pin 24 via 0.047 μF capacitor
4	P0.3	Individually configured GPIO
5	P0.1	Individually configured GPIO
6, 9, 39	V_{bat}	Connected to pin 24 via 0.047 μFshunt capacitor
8	P2.1	GPIO. Port 2 Bit 1
10	RF Bias	RF pin voltage reference
11	RF_p	Differential RF input to/from antenna
12	GND	Ground
13	RF_n	Differential RF to/from antenna
14, 17, 18, 20, 36	NC	
15	P2.0	GPIO. Port 2 Bit 0
19	RESV	Reserved. Must connect to GND
21	P1.0 / D+	GPIO 1.0 / Low speed USB I/O
22	P1.1 / D–	GPIO 1.1 / Low speed USB I/O
23	V_{DD_micro}	4.0–5.5 for 12 MHz CPU/4.75–5.5 for 24 MHz CPU
24	P1.2	Must be configured as 3.3 V output. It must have a 1–2 μF output capacitor
25	P1.3 / nSS	Slave select SPI Pin
26	P1.4 / SCK	Serial Clock Pin from MCU function to radio function
27	IRQ	Interrupt output, configure high/low or GPIO
28	P1.5 / MOSI	Master Out Slave In
29	MISO	Master In Slave Out, from radio function. Can be configured as GPIO

Pin Configuration (continued)

Pin	Name	Function
30	XOUT	Bufferd CLK or GPIO
31	NC	Must be floating
32	P1.6	GPIO. Port 1 Bit 6
33	V_{IO}	I/O interface voltage. Connected to pin 24 via 0.047 μF
34	Reset	Radio Reset. Connected to V_{DD} via 0.47 μF capacitor or to microcontroller GPIO pin. Must have a RESET = HIGH event the very first time power is applied to the radio otherwise the state of the radio function control registers is unknown
35	P1.7	GPIO. Port 1 Bit 7
36	$V_{DD\_1.8}$	Regulated logic bypass. Connected via 0.47 μF to GND
37	GND	Must be connected to ground
38	P0.7	GPIO. Port 0 Bit 7
41	E-pad	Must be connected to GND
42	Corner Tabs	Do not connect corner tabs

PRoC LPstar Functional Overview

The SoC contains a 2.4 GHz 1 Mbps GFSK radio transceiver, packet data buffering, packet framer, DSSS baseband controller, Received Signal Strength Indication (RSSI), and SPI interface for data transfer and device configuration.

The radio supports 98 discrete 1 MHz channels (regulations may limit the use of some of these channels in certain jurisdictions). In DSSS modes the baseband performs DSSS spreading/despreading, while in GFSK Mode (1 Mb/s - GFSK) the baseband performs Start of Frame (SOF), End of Frame (EOF) detection and CRC16 generation and checking. The baseband may also be configured to automatically transmit Acknowledge (ACK) handshake packets whenever a valid packet is received.

When in receive mode, with packet framing enabled, the device is always ready to receive data transmitted at any of the supported bit rates. This enables the implementation of mixed-rate systems in which different devices use different data rates. This also enables the implementation of dynamic data rate systems that use high data rates at shorter distances or in a low-moderate interference environment or both. It changes to lower data rates at longer distances or in high interference environments or both.

The MCU function is an 8-bit Flash programmable microcontroller with integrated low speed USB interface. The instruction set has been optimized specifically for USB operations, although it can be used for a variety of other embedded applications.

The MCU function has up to eight Kbytes of Flash for user's code and up to 256 bytes of RAM for stack space and user variables.

In addition, the MCU function includes a Watchdog timer, a vectored interrupt controller, a 16-bit Free-Running Timer, and 12-bit Programmable Interrupt Timer.

The MCU function supports in-system programming by using the D+ and D– pins as the serial programming mode interface. The programming protocol is not USB.

Functional Block Overview

All the blocks that make up the PRoC LPstar are presented here.

2.4 GHz Radio

The radio transceiver is a dual conversion low IF architecture optimized for power and range/robustness. The radio employs channel matched filters to achieve high performance in the presence of interference. An integrated Power Amplifier (PA) provides up to 0 dBm transmit power, with an output power control range of 30 dB in six steps. The supply current of the device is reduced as the RF output power is reduced.

Table 1. Internal PA Output Power Step Table

PA Setting	Typical Output Power (dBm)
6	0
5	−5
4	−10
3	−15
2	−20
1	−25
0	−30

Frequency Synthesizer

Before transmission or reception may commence, it is necessary for the frequency synthesizer to settle. The settling time varies depending on channel; 25 fast channels are provided with a maximum settling time of 100 μs.

The 'fast channels' (<100 μs settling time) are every third frequency, starting at 2400 MHz up to and including 2472 MHz (for example, 0,3,6,9.......69 and 72).

Baseband and Framer

The baseband and framer blocks provide the DSSS encoding and decoding, SOP generation and reception and CRC16 generation and checking, and EOP detection and length field.

Data Rates and Data Transmission Modes

The SoC supports two different data transmission modes:

■ In GFSK mode, data is transmitted at 1 Mbps, without any DSSS.
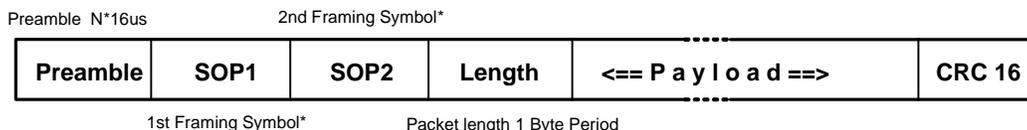

■ In DSSS mode eight bits (8DR, 32 chip) are encoded in each derived code symbol transmitted, resulting in effective 250 Kbps data rate.

32 chip Pseudo Noise (PN) codes are supported. The two data transmission modes apply to the data after the SOP. In particular the length, data, and CRC16 are all sent in the same mode. In general, DSSS reduce packet error rate in any environment.

Link Layer Modes

The CYRF69313 IC device supports the following data packet framing features:

SOP

Packets begin with a two-symbol SoP marker. If framing is disabled then an SOP event is inferred whenever two successive correlations are detected. The SOP_CODE_ADR code used for the SOP is different from that used for the "body" of the packet, and if desired may be a different length. SOP must be configured to be the same length on both sides of the link.

Length

Length field is the first eight bits after the SOP symbol, and is transmitted at the payload data rate. An EoP condition is inferred after reception of the number of bytes defined in the length field, plus two bytes for the CRC16.

CRC16

The device may be configured to append a 16-bit CRC16 to each packet. The CRC16 uses the USB CRC polynomial with the added programmability of the seed. If enabled, the receiver verifies the calculated CRC16 for the payload data against the received value in the CRC16 field. The starting value for the CRC16 calculation is configurable, and the CRC16 transmitted may be calculated using either the loaded seed value or a zero seed; the received data CRC16 is checked against both the configured and zero CRC16 seeds.

CRC16 detects the following errors:

■ Any one bit in error

■ Any two bits in error (irrespective of how far apart, which column, and so on)

■ Any odd number of bits in error (irrespective of the location)

■ An error burst as wide as the checksum itself

Figure 2 shows an example packet with SOP, CRC16 and lengths fields enabled.

Figure 2. Example Default Packet Format

Packet Buffers

Packet data and configuration registers are accessed through the SPI interface. All configuration registers are directly addressed through the address field in the SPI packet. Configuration registers are provided to allow configuration of DSSS PN codes, data rate, operating mode, interrupt masks, interrupt status, and others.

Packet Buffers

All data transmission and reception uses the 16-byte packet buffers—one for transmission and one for reception.

The transmit buffer allows a complete packet of up to 16 bytes of payload data to be loaded in one burst SPI transaction,.This is then transmitted with no further MCU intervention. Similarly, the receive buffer allows an entire packet of payload data up to 16 bytes to be received with no firmware intervention required until packet reception is complete.

The CYRF69313 IC supports packet length of up to 40 bytes; interrupts are provided to allow an MCU to use the transmit and receive buffers as FIFOs. When transmitting a packet longer than 16 bytes, the MCU can load 16 bytes initially, and add further bytes to the transmit buffer as transmission of data creates space in the buffer. Similarly, when receiving packets longer than 16 bytes, the MCU function must fetch received data from the FIFO periodically during packet reception to prevent it from overflowing.

Auto Transaction Sequencer (ATS)

The CYRF69313 IC provides automated support for transmission and reception of acknowledged data packets.

When transmitting a data packet, the device automatically starts the crystal and synthesizer, enters transmit mode, transmits the packet in the transmit buffer, and then automatically switches to receive mode and waits for a handshake packet—and then automatically reverts to sleep mode or idle mode when either an ACK packet is received, or a timeout period expires.

Similarly, when receiving in transaction mode, the device waits in receive mode for a valid packet to be received, then automatically transitions to transmit mode, transmits an ACK packet, and then switches back to receive mode to await the next packet. The contents of the packet buffers are not affected by the transmission or reception of ACK packets.

In each case, the entire packet transaction takes place without any need for MCU firmware action; to transmit data the MCU simply needs to load the data packet to be transmitted, set the length, and set the TX GO bit. Similarly, when receiving packets in transaction mode, firmware simply needs to retrieve the fully received packet in response to an interrupt request indicating reception of a packet.

Interrupts

The radio function provides an interrupt (IRQ) output, which is configurable to indicate the occurrence of various different events. The IRQ pin may be programmed to be either active high or active low, and be either a CMOS or open drain output. The IRQ pin can be multiplexed on the SPI if routed to an external pin.

The radio function features three sets of interrupts: transmit, receive, and system interrupts. These interrupts all share a single pin (IRQ), but can be independently enabled/disabled. In transmit mode, all receive interrupts are automatically disabled, and in receive mode all transmit interrupts are automatically disabled. However, the contents of the enable registers are preserved when switching between transmit and receive modes.

If more than one radio interrupt is enabled at any time, it is necessary to read the relevant status register to determine which event caused the IRQ pin to assert. Even when an interrupt source is disabled, the status of the condition that would otherwise cause an interrupt can be determined by reading the appropriate status register. It is therefore possible to use the devices without making use of the IRQ pin by polling the status register(s) to wait for an event, rather than using the IRQ pin.

The microcontroller function supports 23 maskable interrupts in the vectored interrupt controller. Interrupt sources include a USB bus reset, POR, a programmable interval timer, a 1.024-ms output from the Free Running Timer, three USB endpoints, two capture timers, five GPIO Ports, three GPIO pins, two SPI, a 16-bit free running timer wrap, an internal wakeup timer, and a bus active interrupt. The wakeup timer causes periodic interrupts when enabled. The USB endpoints interrupt after a USB transaction complete is on the bus. The capture timers interrupt whenever a new timer value is saved due to a selected GPIO edge event. A total of eight GPIO interrupts support both TTL or CMOS thresholds. For additional flexibility, on the edge sensitive GPIO pins, the interrupt polarity is programmable to be either rising or falling.

Clocks

The radio function has a 12 MHz crystal (30-ppm or better) directly connected between XTAL and GND without the need for external capacitors. A digital clock out function is provided, with selectable output frequencies of 0.75, 1.5, 3, 6, or 12 MHz. This output may be used to clock an external microcontroller (MCU) or ASIC. This output is enabled by default, but may be disabled.

Following are the requirements for the crystal to be directly connected to XTAL pin and GND:

- Nominal Frequency: 12 MHz

- Operating Mode: Fundamental Mode

- Resonance Mode: Parallel Resonant

- Frequency Stability: ±30 ppm

- Series Resistance: $\leq$60 ohms

- Load Capacitance: 10 pF

- Drive Level:100 μW

The MCU function features an internal oscillator. With the presence of USB traffic, the internal oscillator can be set to precisely tune to USB timing requirements (24 MHz ±1.5%). The clock generator provides the 12 MHz and 24 MHz clocks that remain internal to the microcontroller.

GPIO Interface

The MCU function features up to 20 general purpose I/O (GPIO) pins to support USB, PS/2, and other applications. The I/O pins are grouped into five ports (Port 0 to 4). The pins on Port 0 and Port 1 may each be configured individually while the pins on Ports 2, 3, and 4 may only be configured as a group. Each GPIO port supports high impedance inputs, configurable pull-up, open

drain output, CMOS/TTL inputs, and CMOS output with up to five pins that support programmable drive strength of up to 50 mA sink current. GPIO Port 1 features four pins that interface at a voltage level of 3.3 volts. Additionally, each I/O pin can be used to generate a GPIO interrupt to the microcontroller. Each GPIO port has its own GPIO interrupt vector with the exception of GPIO Port 0. GPIO Port 0 has three dedicated pins that have independent interrupt vectors (P0.3–P0.4).

Power-on Reset

The power-on reset (POR) circuit detects logic when power is applied to the device, resets the logic to a known state, and begins executing instructions at Flash address 0x0000. When power falls below a programmable trip voltage, it generates reset or may be configured to generate interrupt. The Watchdog timer can be used to ensure the firmware never gets stalled in an infinite loop.

Power Management

The device draws its power supply from the USB V_{bus} line. The V_{bus} supplies power to the MCU function, which has an internal 3.3 V regulator. This 3.3 V is supplied to the radio function via P1.2 after proper filtering as shown in Figure 3

Figure 3. Power Management From Internal Regulator
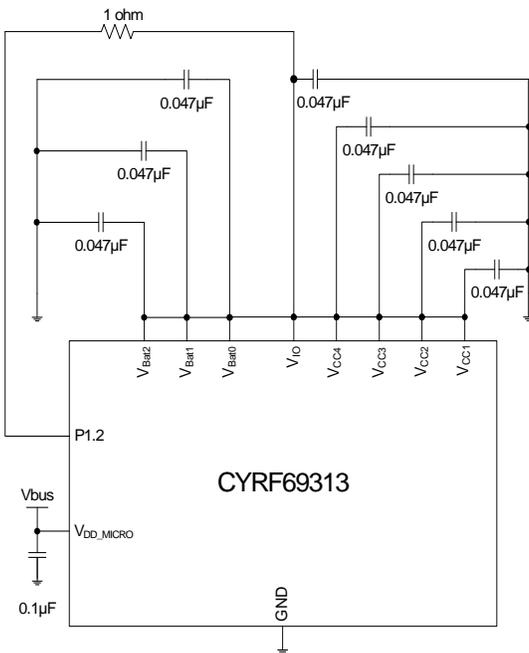

Timers

The free-running 16-bit timer provides two interrupt sources: the programmable interval timer with 1 μs resolution and the 1.024 ms outputs. The timer can be used to measure the duration of an event under firmware control by reading the timer at the start and at the end of an event, then calculating the difference between the two values.

USB Interface

The MCU function includes an integrated USB serial interface engine (SIE) that allows the chip to easily interface to a USB host. The hardware supports one USB device address with three endpoints.

Low Noise Amplifier (LNA) and Received Signal Strength Indication (RSSI)

The gain of the receiver may be controlled directly by clearing the AGC EN bit and writing to the low noise amplifier (LNA) bit of the RX_CFG_ADR register. When the LNA bit is cleared, the receiver gain is reduced by approximately 20 dB, allowing accurate reception of very strong received signals (for example when operating a receiver very close to the transmitter). An additional 20 dB of receiver attenuation can be added by setting the Attenuation (ATT) bit; this allows data reception to be limited to devices at very short ranges. Disabling AGC and enabling LNA is recommended unless receiving from a device using external PA.

The RSSI register returns the relative signal strength of the on-channel signal power.

When receiving, the device may be configured to automatically measure and store the relative strength of the signal being received as a 5-bit value. When enabled, an RSSI reading is taken and may be read through the SPI interface. An RSSI reading is taken automatically when the start of a packet is detected. In addition, a new RSSI reading is taken every time the previous reading is read from the RSSI register, allowing the background RF energy level on any channel to be easily measured when RSSI is read when no signal is being received. A new reading can occur as fast as once every 12 μs.

SPI Interface

The SPI interface between the MCU function and the radio function is a 3-wire SPI Interface. The three pins are MOSI (Master Out Slave In), SCK (Serial Clock), SS (Slave Select). There is an alternate 4-wire MISO Interface that requires the connection of two external pins. The SPI interface is controlled by configuring the SPI Configure Register (SICR Address: 0x3D).

3-Wire SPI Interface

The radio function receives a clock from the MCU function on the SCK pin. The MOSI pin is multiplexed with the MISO pin. Bidirectional data transfer takes place between the MCU function and the radio function through this multiplexed MOSI pin. When using this mode the user firmware should ensure that the MOSI pin on the MCU function is in a high impedance state, except when the MCU is actively transmitting data. Firmware must also control the direction of data flow and switch directions between MCU function and radio function by setting the SWAP bit [Bit 7] of the SPI Configure Register. The SS pin is asserted prior to initiating a data transfer between the MCU function and the radio function. The IRQ function may be optionally multiplexed with the MOSI pin; when this option is enabled the IRQ function is not available while the SS pin is low. When using this configuration, user firmware should ensure that the MOSI function on MCU function is in a high impedance state whenever SS is high.

Figure 4. 3-Wire SPI Mode
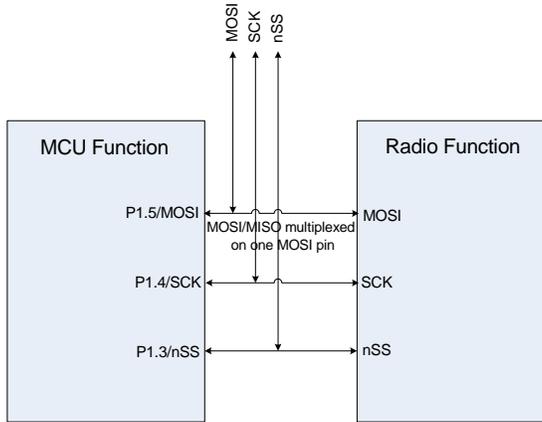

Four-Wire SPI Interface

The 4-wire SPI communications interface consists of MOSI, MISO, SCK, and SS.

The device receives SCK from the MCU function on the SCK pin. Data from the MCU function is shifted in on the MOSI pin. Data to the MCU function is shifted out on the MISO pin. The active low SS pin must be asserted for the two functions to communicate. The IRQ function may be optionally multiplexed with the MOSI pin; when this option is enabled the IRQ function is not available while the SS pin is low. When using this configuration, user firmware should ensure that the MOSI function on MCU function is in a high impedance state whenever SS is high.

Figure 5. 4-WIRE SPI Mode

This connection is external to the PRoC LPstar Chip
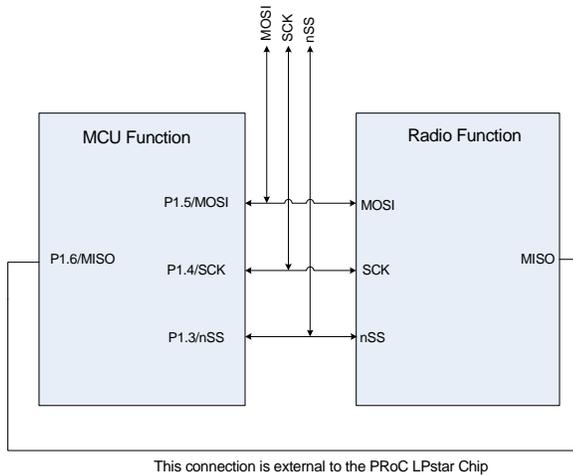

SPI Communication and Transactions

The SPI transactions can be single byte or multi-byte. The MCU function initiates a data transfer through a Command/Address byte. The following bytes are data bytes. The SPI transaction format is shown in Figure 2.

The DIR bit specifies the direction of data transfer. 0 = Master reads from slave. 1 = Master writes to slave.

The INC bit helps to read or write consecutive bytes from contiguous memory locations in a single burst mode operation.

If Slave Select is asserted and INC = 1, then the master MCU function reads a byte from the radio, the address is incremented by a byte location, and then the byte at that location is read, and so on. If Slave Select is asserted and INC = 0, then the MCU function reads/writes the bytes in the same register in burst mode, but if it is a register file then it reads/writes the bytes in that register file.

The SPI interface between the radio function and the MCU is not dependent on the internal 12 MHz oscillator of the radio. Therefore, radio function registers can be read from or written into while the radio is in sleep mode.

SPI I/O Voltage References

The SPI interfaces between MCU function and the radio and the IRQ and RST have a separate voltage reference V_{IO}, enabling the radio function to directly interface with the MCU function, which operates at higher supply voltage. The internal SPIO pins between the MCU function and radio function should be connected with a regulated voltage of 3.3 V (by setting [bit4] of Registers P13CR, P14CR, P15CR, and P16CR of the MCU function) and the internal 3.3 V regulator of the MCU function should be turned on.

SPI Connects to External Devices

The three SPI wires, MOSI, SCK, and SS are also drawn out of the package as external pins to allow the user to interface their own external devices (such as optical sensors and others) through SPI. The radio function also has its own SPI wires MISO and IRQ, which can be used to send data back to the MCU function or send an interrupt request to the MCU function. They can also be configured as GPIO pins.

Table 2. SPI Transaction Format

	Byte 1			Byte 1+N
Bit#	7	6	[5:0]	[7:0]
Bit Name	DIR	INC	Address	Data

CPU Architecture

This family of microcontrollers is based on a high performance, 8-bit, Harvard-architecture microprocessor. Five registers control the primary operation of the CPU core. These registers are affected by various instructions, but are not directly accessible through the register space by the user.

Table 3. CPU Registers and Register Names

Register	Register Name
Flags	CPU_F
Program Counter	CPU_PC
Accumulator	CPU_A
Stack Pointer	CPU_SP
Index	CPU_X

The 16-bit Program Counter Register (CPU_PC) allows for direct addressing of the full eight Kbytes of program memory space.

The Accumulator Register (CPU_A) is the general purpose register that holds the results of instructions that specify any of the source addressing modes.

The Index Register (CPU_X) holds an offset value that is used in the indexed addressing modes. Typically, this is used to address a block of data within the data memory space.

The Stack Pointer Register (CPU_SP) holds the address of the current top-of-stack in the data memory space. It is affected by the PUSH, POP, LCALL, CALL, RETI, and RET instructions, which manage the software stack. It can also be affected by the SWAP and ADD instructions.

The Flag Register (CPU_F) has three status bits: Zero Flag bit [1]; Carry Flag bit [2]; Supervisory State bit [3]. The Global Interrupt Enable bit [0] is used to globally enable or disable interrupts. The user cannot manipulate the Supervisory State status bit [3]. The flags are affected by arithmetic, logic, and shift operations. The manner in which each flag is changed is dependent upon the instruction being executed (for example, AND, OR, XOR). See .

CPU Registers

Flags Register

The Flags Register can only be set or reset with logical instruction.

Table 4. CPU Flags Register (CPU_F) [R/W]

Bit #	7	6	5	4	3	2	1	0
Field	Reserved			XIO	Super	Carry	Zero	Global IE
Read/Write	–	–	–	R/W	R	RW	RW	RW
Default	0	0	0	0	0	0	1	0

Bits 7:5   Reserved

Bit 4   XIO
    Set by the user to select between the register banks
    0 = Bank 0
    1 = Bank 1

Bit 3   Super
    Indicates whether the CPU is executing user code or Supervisor Code. (This code cannot be accessed directly by the user.)
    0 = User Code
    1 = Supervisor Code

Bit 2   Carry
    Set by CPU to indicate whether there has been a carry in the previous logical/arithmetic operation
    0 = No Carry
    1 = Carry

Bit 1   Zero
    Set by CPU to indicate whether there has been a zero result in the previous logical/arithmetic operation
    0 = Not Equal to Zero
    1 = Equal to Zero

Bit 0   Global IE
    Determines whether all interrupts are enabled or disabled
    0 = Disabled
    1 = Enabled

Note CPU_F register is only readable with explicit register address 0xF7. The *OR F, expr and AND F, expr* instructions must be used to set and clear the CPU_F bits

Accumulator Register

Table 5. CPU Accumulator Register (CPU_A)

Bit #	7	6	5	4	3	2	1	0
Field	CPU Accumulator [7:0]							
Read/Write	–	–	–	–	–	–	–	–
Default	0	0	0	0	0	0	0	0

Bits 7:0 CPU Accumulator [7:0]
8-bit data value holds the result of any logical/arithmetic instruction that uses a source addressing mode

Index Register

Table 6. CPU X Register (CPU_X)

Bit #	7	6	5	4	3	2	1	0
Field	X [7:0]							
Read/Write	–	–	–	–	–	–	–	–
Default	0	0	0	0	0	0	0	0

Bits 7:0 X [7:0]
8-bit data value holds an index for any instruction that uses an indexed addressing mode

Stack Pointer Register

Table 7. CPU Stack Pointer Register (CPU_SP)

Bit #	7	6	5	4	3	2	1	0
Field	Stack Pointer [7:0]							
Read/Write	–	–	–	–	–	–	–	–
Default	0	0	0	0	0	0	0	0

Bits 7:0 Stack Pointer [7:0]
8-bit data value holds a pointer to the current top-of-stack

CPU Program Counter High Register

Table 8. CPU Program Counter High Register (CPU_PCH)

Bit #	7	6	5	4	3	2	1	0
Field	Program Counter [15:8]							
Read/Write	–	–	–	–	–	–	–	–
Default	0	0	0	0	0	0	0	0

Bits 7:0 Program Counter [15:8]
8-bit data value holds the higher byte of the program counter

CPU Program Counter Low Register

Table 9. CPU Program Counter Low Register (CPU_PCL)

Bit #	7	6	5	4	3	2	1	0
Field	Program Counter [7:0]							
Read/Write	–	–	–	–	–	–	–	–
Default	0	0	0	0	0	0	0	0

Bits 7:0 Program Counter [7:0]
8-bit data value holds the lower byte of the program counter

Addressing Modes

Examples of the different addressing modes are discussed in this section and example code is given.

Source Immediate

The result of an instruction using this addressing mode is placed in the A register, the F register, the SP register, or the X register, which is specified as part of the instruction opcode. Operand 1 is an immediate value that serves as a source for the instruction. Arithmetic instructions require two sources. Instructions using this addressing mode are two bytes in length.

Table 10. Source Immediate

Opcode	Operand 1
Instruction	Immediate Value

Examples

```
ADD   A,  7   ;In this case, the immediate value
              ;of 7 is added with the Accumulator,
              ;and the result is placed in the
              ;Accumulator.

MOV  X,  8    ;In this case, the immediate value
              ;of 8 is moved to the X register.

AND  F,  9    ;In this case, the immediate value
              ;of 9 is logically ANDed with the F
              ;register and the result is placed
              ;in the F register.
```

Source Direct

The result of an instruction using this addressing mode is placed in either the A register or the X register, which is specified as part of the instruction opcode. Operand 1 is an address that points to a location in either the RAM memory space or the register space that is the source for the instruction. Arithmetic instructions require two sources; the second source is the A register or X register specified in the opcode. Instructions using this addressing mode are two bytes in length.

Table 11. Source Direct

Opcode	Operand 1
Instruction	Source Address

Examples

```
ADD  A,  [7]     ;In this case, the value in
                 ;the RAM memory location at
                 ;address 7 is added with the
                 ;Accumulator, and the result
                 ;is placed in the Accumulator.

MOV  X,  REG[8]  ;In this case, the value in
                 ;the register space at address
                 ;8 is moved to the X register.
```

Source Indexed

The result of an instruction using this addressing mode is placed in either the A register or the X register, which is specified as part of the instruction opcode. Operand 1 is added to the X register forming an address that points to a location in either the RAM memory space or the register space that is the source for the instruction. Arithmetic instructions require two sources; the second source is the A register or X register specified in the opcode. Instructions using this addressing mode are two bytes in length.

Table 12. Source Indexed

Opcode	Operand 1
Instruction	Source Index

Examples

```
ADD   A,   [X+7]    ;In this case, the value in
                    ;the memory location at
                    ;address X + 7 is added with
                    ;the Accumulator, and the
                    ;result is placed in the
                    ;Accumulator.

MOV   X,   REG[X+8] ;In this case, the value in
                    ;the register space at
                    ;address X + 8 is moved to
                    ;the X register.
```

Destination Direct

The result of an instruction using this addressing mode is placed within either the RAM memory space or the register space. Operand 1 is an address that points to the location of the result. The source for the instruction is either the A register or the X register, which is specified as part of the instruction opcode. Arithmetic instructions require two sources; the second source is the location specified by Operand 1. Instructions using this addressing mode are two bytes in length.

Table 13. Destination Direct

Opcode	Operand 1
Instruction	Destination Address

Examples

```
ADD   [7],   A   ;In this case, the value in
                 ;the memory location at
                 ;address 7 is added with the
                 ;Accumulator, and the result
                 ;is placed in the memory
                 ;location at address 7. The
                 ;Accumulator is unchanged.

MOV   REG[8], A  ;In this case, the Accumula-
                 ;tor is moved to the regis-
                 ;ter space location at
                 ;address 8. The Accumulator
                 ;is unchanged.
```

Destination Indexed

The result of an instruction using this addressing mode is placed within either the RAM memory space or the register space. Operand 1 is added to the X register forming the address that points to the location of the result. The source for the instruction is the A register. Arithmetic instructions require two sources; the second source is the location specified by Operand 1 added with the X register. Instructions using this addressing mode are two bytes in length.

Table 14. Destination Indexed

Opcode	Operand 1
Instruction	Destination Index

Example

```
ADD  [X+7],  A  ;In this case, the value in the
                ;memory location at address X+7
                ;is added with the Accumulator,
                ;and the result is placed in
                ;the memory location at address
                ;x+7. The Accumulator is
                ;unchanged.
```

Destination Direct Source Immediate

The result of an instruction using this addressing mode is placed within either the RAM memory space or the register space. Operand 1 is the address of the result. The source for the instruction is Operand 2, which is an immediate value. Arithmetic instructions require two sources; the second source is the location specified by Operand 1. Instructions using this addressing mode are three bytes in length.

Table 15. Destination Direct Immediate

Opcode	Operand 1	Operand 2
Instruction	Destination Address	Immediate Value

Examples

```
ADD  [7],    5  ;In this case, value in the
                ;memory location at address 7 is
                ;added to the immediate value of
                ;5, and the result is placed in
                ;the memory location at address 7.

MOV  REG[8], 6  ;In this case, the immediate
                ;value of 6 is moved into the
                ;register space location at
                ;address 8.
```

Destination Indexed Source Immediate

The result of an instruction using this addressing mode is placed within either the RAM memory space or the register space. Operand 1 is added to the X register to form the address of the result. The source for the instruction is Operand 2, which is an immediate value. Arithmetic instructions require two sources; the second source is the location specified by Operand 1 added with the X register. Instructions using this addressing mode are three bytes in length.

Table 16. Destination Indexed Immediate

Opcode	Operand 1	Operand 2
Instruction	Destination Index	Immediate Value

Examples

```
ADD  [X+7],   5  ;In this case, the value in
                 ;the memory location at
                 ;address X+7 is added with
                 ;the immediate value of 5,
                 ;and the result is placed
                 ;in the memory location at
                 ;address X+7.

MOV  REG[X+8], 6 ;In this case, the immedi-
                 ;ate value of 6 is moved
                 ;into the location in the
                 ;register space at
                 ;address X+8.
```

Destination Direct Source Direct

The result of an instruction using this addressing mode is placed within the RAM memory. Operand 1 is the address of the result. Operand 2 is an address that points to a location in the RAM memory that is the source for the instruction. This addressing mode is only valid on the MOV instruction. The instruction using this addressing mode is three bytes in length.

Table 17. Destination Direct Source Direct

Opcode	Operand 1	Operand 2
Instruction	Destination Address	Source Address

Example

```
MOV  [7], [8]  ;In this case, the value in the
               ;memory location at address 8 is
               ;moved to the memory location at
               ;address 7.
```

Source Indirect Post Increment

The result of an instruction using this addressing mode is placed in the Accumulator. Operand 1 is an address pointing to a location within the memory space, which contains an address (the indirect address) for the source of the instruction. The indirect address is incremented as part of the instruction execution. This addressing mode is only valid on the MVI instruction. The instruction using this addressing mode is two bytes in length. Refer to the *PSoC Designer: Assembly Language User Guide* for further details on MVI instruction.

Table 18. Source Indirect Post Increment

Opcode	Operand 1
Instruction	Source Address Address

Example

```
MVI   A,  [8]   ;In this case, the value in the
                ;memory location at address 8 is
                ;an indirect address. The memory
                ;location pointed to by the indi-
                ;rect address is moved into the
                ;Accumulator. The indirect
                ;address is then incremented.
```

Destination Indirect Post Increment

The result of an instruction using this addressing mode is placed within the memory space. Operand 1 is an address pointing to a location within the memory space, which contains an address (the indirect address) for the destination of the instruction. The indirect address is incremented as part of the instruction execution. The source for the instruction is the Accumulator. This addressing mode is only valid on the MVI instruction. The instruction using this addressing mode is two bytes in length.

Table 19. Destination Indirect Post Increment

Opcode	Operand 1
Instruction	Destination Address Address

Example

```
MVI   [8],  A    ;In this case, the value in
                 ;the memory location at
                 ;address 8 is an indirect
                 ;address. The Accumulator is
                 ;moved into the memory loca-
                 ;tion pointed to by the indi-
                 ;rect address. The indirect
                 ;address is then incremented.
```

Instruction Set Summary

The instruction set is summarized in Table 20 numerically and serves as a quick reference. If more information is needed, the Instruction Set Summary tables are described in detail in the *PSoC Designer Assembly Language User Guide* (available on www.cypress.com).

Table 20. Instruction Set Summary Sorted Numerically by Opcode Order[1, 2]

Opcode Hex	Cycles	Bytes	Instruction Format	Flags	Opcode Hex	Cycles	Bytes	Instruction Format	Flags	Opcode Hex	Cycles	Bytes	Instruction Format	Flags

										Fx	13	2	INDEX	Z

Notes
1. Interrupt routines take 13 cycles before execution resumes at interrupt vector table.
2. The number of cycles required by an instruction is increased by one for instructions that span 256-byte boundaries in the Flash memory space.

Memory Organization

Top of RAM Memory 0xFF
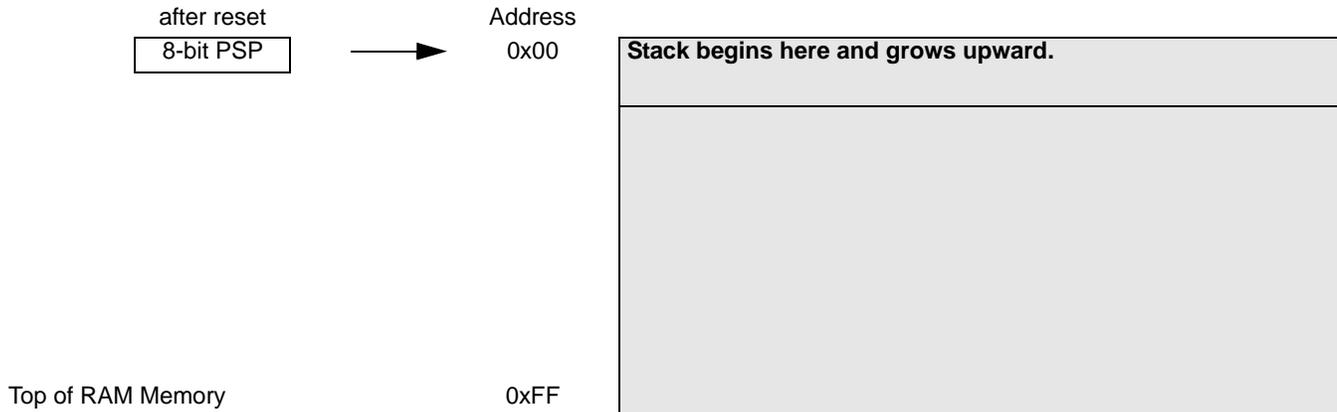

Flash

This section describes the Flash block of the CYRF69313. Much of the user-visible Flash functionality, including programming and security, are implemented in the M8C Supervisory Read Only Memory (SROM). CYRF69313 Flash has an endurance of 1000 cycles and 10 year data retention.

Flash Programming and Security

All Flash programming is performed by code in the SROM. The registers that control the Flash programming are only visible to the M8C CPU when it is executing out of SROM. This makes it impossible to read, write, or erase the Flash by bypassing the security mechanisms implemented in the SROM.

Customer firmware can only program the Flash via SROM calls. The data or code images can be sourced by way of any interface with the appropriate support firmware. This type of programming requires a 'bootloader'—a piece of firmware resident on the Flash. For safety reasons this bootloader should not be overwritten during firmware rewrites.

The Flash provides four auxiliary rows that are used to hold Flash block protection flags, boot time calibration values, configuration tables, and any device values. The routines for accessing these auxiliary rows are documented in the SROM section. The auxiliary rows are not affected by the device erase function.

In-System Programming

Most designs that include an CYRF69313 part have a USB connector attached to the USB D+/D− pins on the device. These designs require the ability to program or reprogram a part through these two pins alone.

CYRF69313 device enables this type of in-system programming by using the D+ and D− pins as the serial programming mode interface. This allows an external controller to cause the CYRF69313 part to enter serial programming mode and then to use the test queue to issue Flash access functions in the SROM. The programming protocol is not USB.

SROM

The SROM holds code that is used to boot the part, calibrate circuitry, and perform Flash operations. (Table 22 lists the SROM functions.) The functions of the SROM may be accessed in normal user code or operating from Flash. The SROM exists in a separate memory space from user code. The SROM functions are accessed by executing the Supervisory System Call instruction (SSC), which has an opcode of 00h. Prior to executing the SSC, the M8C's accumulator needs to be loaded with the desired SROM function code from Table 22. Undefined functions causes a HALT if called from user code. The SROM functions are executing code with calls; therefore, the functions require stack space. With the exception of Reset, all of the SROM functions have a *parameter block* in SRAM that must be configured before executing the SSC. Table 23 lists all possible parameter block variables. The meaning of each parameter, with regards to a specific SROM function, is described later in this section.

Table 22. SROM Function Codes

Function Code	Function Name	Stack Space
00h	SWBootReset	0
01h	ReadBlock	7
02h	WriteBlock	10
03h	EraseBlock	9
05h	EraseAll	11
06h	TableRead	3
07h	CheckSum	3

Two important variables that are used for all functions are KEY1 and KEY2. These variables are used to help discriminate between valid SSCs and inadvertent SSCs. KEY1 must always have a value of 3Ah, while KEY2 must have the same value as the stack pointer when the SROM function begins execution. This would be the Stack Pointer value when the SSC opcode is executed, plus three. If either of the keys do not match the expected values, the M8C halts (with the exception of the SWBootReset function). The following code puts the correct

value in KEY1 and KEY2. The code starts with a halt, to force the program to jump directly into the setup code and not run into it.

```
halt
SSCOP: mov [KEY1], 3ah
mov X, SP
mov A, X
add A, 3
mov [KEY2], A
```

Table 23. SROM Function Parameters

Variable Name	SRAM Address
Key1/Counter/Return Code	0,F8h
Key2/TMP	0,F9h
BlockID	0,FAh
Pointer	0,FBh
Clock	0,FCh
Mode	0,FDh
Delay	0,FEh
PCL	0,FFh

The SROM also features Return Codes and Lockouts.

Return Codes

Return codes aid in the determination of success or failure of a particular function. The return code is stored in KEY1's position in the parameter block. The CheckSum and TableRead functions do not have return codes because KEY1's position in the parameter block is used to return other data.

Table 24. SROM Return Codes

Return Code	Description
00h	Success
01h	Function not allowed due to level of protection on block
02h	Software reset without hardware reset
03h	Fatal error, SROM halted

Read, write, and erase operations may fail if the target block is read or write protected. Block protection levels are set during device programming.

The EraseAll function overwrites data in addition to leaving the entire user Flash in the erase state. The EraseAll function loops through the number of Flash macros in the product, executing the following sequence: erase, bulk program all zeros, erase. After all the user space in all the Flash macros are erased, a second loop erases and then programs each protection block with zeros.

SROM Function Descriptions

All SROM functions are described in the following sections.

SWBootReset Function

The SROM function, SWBootReset, is the function that is responsible for transitioning the device from a reset state to running user code. The SWBootReset function is executed whenever the SROM is entered with an M8C accumulator value

of 00h; the SRAM parameter block is not used as an input to the function. This happens, by design, after a hardware reset, because the M8C's accumulator is reset to 00h or when user code executes the SSC instruction with an accumulator value of 00h. The SWBootReset function does not execute when the SSC instruction is executed with a bad key value and a nonzero function code. A CYRF69313 device executes the HALT instruction if a bad value is given for either KEY1 or KEY2.

The SWBootReset function verifies the integrity of the calibration data by way of a 16-bit checksum, before releasing the M8C to run user code.

ReadBlock Function

The ReadBlock function is used to read 64 contiguous bytes from Flash—a block.

The first thing this function does is to check the protection bits and determine if the desired BLOCKID is readable. If read protection is turned on, the ReadBlock function exits, setting the accumulator and KEY2 back to 00h. KEY1 has a value of 01h, indicating a read failure. If read protection is not enabled, the function reads 64 bytes from the Flash using a ROMX instruction and store the results in SRAM using an MVI instruction. The first of the 64 bytes is stored in SRAM at the address indicated by the value of the POINTER parameter. When the ReadBlock completes successfully, the accumulator, KEY1, and KEY2 all have a value of 00h.

Table 25. ReadBlock Parameters

Name	Address	Description
KEY1	0,F8h	3Ah
KEY2	0,F9h	Stack Pointer value, when SSC is executed
BLOCKID	0,FAh	Flash block number
POINTER	0,FBh	First of 64 addresses in SRAM where returned data should be stored

WriteBlock Function

The WriteBlock function is used to store data in the Flash. Data is moved 64 bytes at a time from SRAM to Flash using this function. The first thing the WriteBlock function does is to check the protection bits and determine if the desired BLOCKID is writable. If write protection is turned on, the WriteBlock function exits, setting the accumulator and KEY2 back to 00h. KEY1 has a value of 01h, indicating a write failure. The configuration of the WriteBlock function is straightforward. The BLOCKID of the Flash block, where the data is stored, must be determined and stored at SRAM address FAh.

The SRAM address of the first of the 64 bytes to be stored in Flash must be indicated using the POINTER variable in the parameter block (SRAM address FBh). Finally, the CLOCK and DELAY values must be set correctly. The CLOCK value determines the length of the write pulse that is used to store the data in the Flash. The CLOCK and DELAY values are dependent on the CPU speed. Refer to 'Clocking' Section for additional information.

Table 26. WriteBlock Parameters

Name	Address	Description
KEY1	0,F8h	3Ah
KEY2	0,F9h	Stack Pointer value, when SSC is executed
BLOCKID	0,FAh	8 KB Flash block number (00h–7Fh) 4 KB Flash block number (00h–3Fh) 3 KB Flash block number (00h–2Fh)
POINTER	0,FBh	First of 64 addresses in SRAM, where the data to be stored in Flash is located prior to calling WriteBlock
CLOCK	0,FCh	Clock divider used to set the write pulse width
DELAY	0,FEh	For a CPU speed of 12 MHz set to 56h

EraseBlock Function

The EraseBlock function is used to erase a block of 64 contiguous bytes in Flash. The first thing the EraseBlock function does is to check the protection bits and determine if the desired BLOCKID is writable. If write protection is turned on, the Erase-Block function exits, setting the accumulator and KEY2 back to 00h. KEY1 has a value of 01h, indicating a write failure. The EraseBlock function is only useful as the first step in programming. Erasing a block does not cause data in a block to be one hundred percent unreadable. If the objective is to obliterate data in a block, the best method is to perform an Erase-Block followed by a WriteBlock of all zeros.

To setup the parameter block for the EraseBlock function, correct key values must be stored in KEY1 and KEY2. The block number to be erased must be stored in the BLOCKID variable and the CLOCK and DELAY values must be set based on the current CPU speed.

Table 27. EraseBlock Parameters

Name	Address	Description
KEY1	0,F8h	3Ah
KEY2	0,F9h	Stack Pointer value when SSC is executed
BLOCKID	0,FAh	Flash block number (00h–7Fh)
CLOCK	0,FCh	Clock divider used to set the erase pulse width
DELAY	0,FEh	For a CPU speed of 12 MHz set to 56h

ProtectBlock Function

The CYRF69313 device offers Flash protection on a block-by-block basis. Table 28 lists the protection modes available. In the table, ER and EW are used to indicate the ability to perform external reads and writes. For internal writes, IW is used. Internal reading is always permitted by way of the ROMX instruction. The ability to read by way of the SROM ReadBlock function is indicated by SR. The protection level is stored in two bits according to Table 28. These bits are bit packed into the 64 bytes of the protection block. Therefore, each protection block byte stores the protection level for four Flash blocks. The bits are packed into a byte, with the lowest numbered block's protection level stored in the lowest numbered bits.

The first address of the protection block contains the protection level for blocks 0 through 3; the second address is for blocks 4 through 7. The 64th byte stores the protection level for blocks 252 through 255.

Table 28. Protection Modes

Mode	Settings	Description	Marketing
00b	SR ER EW IW	Unprotected	Unprotected
01b	S̅R̅ ER EW IW	Read protect	Factory upgrade
10b	S̅R̅ E̅R̅ EW IW̅	Disable external write	Field upgrade
11b	S̅R̅ E̅R̅ E̅W̅ IW	Disable internal write	Full protection

7	6	5	4	3	2	1	0
Block n+3		Block n+2		Block n+1		Block n	

The level of protection is only decreased by an EraseAll, which places zeros in all locations of the protection block. To set the level of protection, the ProtectBlock function is used. This function takes data from SRAM, starting at address 80h, and ORs it with the current values in the protection block. The result of the OR operation is then stored in the protection block. The EraseBlock function does not change the protection level for a block. Because the SRAM location for the protection data is fixed and there is only one protection block per Flash macro, the ProtectBlock function expects very few variables in the parameter block to be set prior to calling the function. The parameter block values that must be set, besides the keys, are the CLOCK and DELAY values.

Table 29. ProtectBlock Parameters

Name	Address	Description
KEY1	0,F8h	3Ah
KEY2	0,F9h	Stack Pointer value when SSC is executed
CLOCK	0,FCh	Clock divider used to set the write pulse width
DELAY	0,FEh	For a CPU speed of 12 MHz set to 56h

EraseAll Function

The EraseAll function performs a series of steps that destroy the user data in the Flash macros and resets the protection block in each Flash macro to all zeros (the unprotected state). The EraseAll function does not affect the three hidden blocks above the protection block in each Flash macro. The first of these four hidden blocks is used to store the protection table for its eight Kbytes of user data.

The EraseAll function begins by erasing the user space of the Flash macro with the highest address range. A bulk program of all zeros is then performed on the same Flash macro, to destroy all traces of the previous contents. The bulk program is followed by a second erase that leaves the Flash macro in a state ready for writing. The erase, program, erase sequence is then performed on the next lowest Flash macro in the address space if it exists. Following the erase of the user space, the protection block for the Flash macro with the highest address range is

erased. Following the erase of the protection block, zeros are written into every bit of the protection table. The next lowest Flash macro in the address space then has its protection block erased and filled with zeros.

The end result of the EraseAll function is that all user data in the Flash is destroyed and the Flash is left in an unprogrammed state, ready to accept one of the various write commands. The protection bits for all user data are also reset to the zero state.

The parameter block values that must be set, besides the keys, are the CLOCK and DELAY values.

Table 30. EraseAll Parameters

Name	Address	Description
KEY1	0,F8h	3Ah
KEY2	0,F9h	Stack Pointer value when SSC is executed
CLOCK	0,FCh	Clock divider used to set the write pulse width
DELAY	0,FEh	For a CPU speed of 12 MHz set to 56h

TableRead Function

The TableRead function gives the user access to part specific data stored in the Flash during manufacturing. It also returns a Revision ID for the die (not to be confused with the Silicon ID).

Table 31. Table Read Parameters

Name	Address	Description
KEY1	0,F8h	3Ah
KEY2	0,F9h	Stack Pointer value when SSC is executed
BLOCKID	0,FAh	Table number to read

The table space for the CYRF69313 is simply a 64-byte row broken up into eight tables of eight bytes. The tables are numbered zero through seven. All user and hidden blocks in the CYRF69313 parts consist of 64 bytes.

An internal table holds the Silicon ID and returns the Revision ID. The Silicon ID is returned in SRAM, while the Revision ID is returned in the CPU_A and CPU_X registers. The Silicon ID is a value placed in the table by programming the Flash and is controlled by Cypress Semiconductor Product Engineering. The Revision ID is hard coded into the SROM. The Revision ID is discussed in more detail later in this section.

An internal table holds alternate trim values for the device and returns a one-byte internal revision counter. The internal revision counter starts out with a value of zero and is incremented each time one of the other revision numbers is not incremented. It is reset to zero each time one of the other revision numbers is incremented. The internal revision count is returned in the CPU_A register. The CPU_X register is always set to FFh when trim values are read. The BLOCKID value, in the parameter block, is used to indicate which table should be returned to the user. Only the three least significant bits of the BLOCKID parameter are used by the TableRead function for the CYRF69313. The upper five bits are ignored. When the function is called, it transfers bytes from the table to SRAM addresses F8h–FFh.

The M8C's A and X registers are used by the TableRead function to return the die's Revision ID. The Revision ID is a 16-bit value hard coded into the SROM that uniquely identifies the die's design.

Checksum Function

The Checksum function calculates a 16-bit checksum over a user specifiable number of blocks, within a single Flash macro (Bank) starting from block zero. The BLOCKID parameter is used to pass in the number of blocks to calculate the checksum over. A BLOCKID value of 1 calculates the checksum of only block 0, while a BLOCKID value of 0 calculates the checksum of all 256 user blocks. The 16-bit checksum is returned in KEY1 and KEY2. The parameter KEY1 holds the lower eight bits of the checksum and the parameter KEY2 holds the upper eight bits of the checksum.

The checksum algorithm executes the following sequence of three instructions over the number of blocks times 64 to be checksummed.

```
romx
  add [KEY1], A
adc [KEY2], 0
```

Table 32. Checksum Parameters

Name	Address	Description
KEY1	0,F8h	3Ah
KEY2	0,F9h	Stack Pointer value when SSC is executed
BLOCKID	0,FAh	Number of Flash blocks to calculate checksum on

SROM Table Read Description

    jmp .terminate
```

Clocking

The CYRF69313 internal oscillator outputs two frequencies, the Internal 24 MHz Oscillator and the 32 kHz Low power Oscillator.

The Internal 24 MHz Oscillator is designed such that it may be trimmed to an output frequency of 24 MHz over temperature and voltage variation. With the presence of USB traffic, the Internal 24 MHz Oscillator can be set to precisely tune to USB timing requirements (24 MHz ± 1.5%). Without USB traffic, the Internal 24 MHz Oscillator accuracy is 24 MHz ± 5% (between 0 °C – 70 °C). No external components are required to achieve this level of accuracy.

The internal low speed oscillator of nominally 32 kHz provides a slow clock source for the CYRF69313 in suspend mode, particularly to generate a periodic wakeup interrupt and also to provide a clock to sequential logic during power-up and power-down events when the main clock is stopped. In addition, this oscillator can also be used as a clocking source for the Interval Timer clock (ITMRCLK) and Capture Timer clock (TCAPCLK). The 32 kHz Low power Oscillator can operate in low power mode or can provide a more accurate clock in normal mode. The Internal 32 kHz Low power Oscillator accuracy ranges (between 0 °C – 70° C) as follows:

5 V Normal mode: –8% to + 16%

5 V LPstar mode: +12% to + 48%

When using the 32 kHz oscillator the PITMRL/H should be read until two consecutive readings match before sending/receiving data. The following firmware example assumes the developer is interested in the lower byte of the PIT.

```
Read_PIT_counter:
mov A, reg[PITMRL]

ret
```

Figure 8. Clock Block Diagram
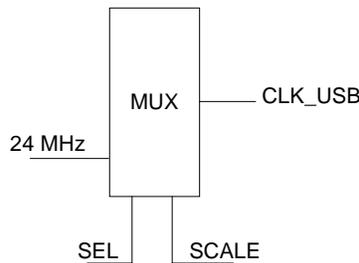

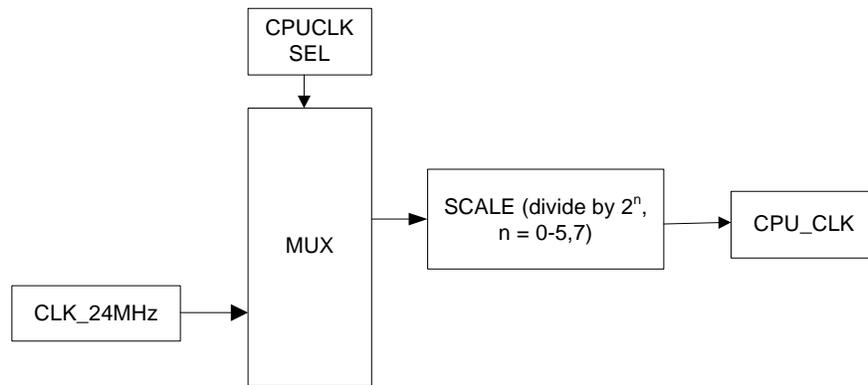

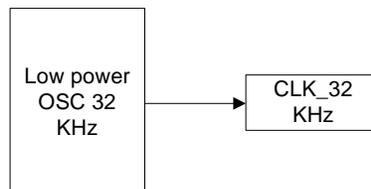

Clock Architecture Description

The CYRF69313 clock selection circuitry allows the selection of independent clocks for the CPU, USB, Interval Timers, and Capture Timers.

The CPU clock, CPUCLK, can be sourced from the Internal 24 MHz Oscillator. This clock source can optionally be divided by 2^n where n is 0–5,7 (see Table 36).

USBCLK, which must be 12 MHz for the USB SIE to function properly, can be sourced by the Internal 24 MHz Oscillator. An optional divide-by-two allows the use of the 24 MHz source.

The Interval Timer clock (ITMRCLK), can be sourced from the Internal 24 MHz Oscillator, the Internal 32 kHz Low power Oscillator, except when in sleep mode, or from the timer capture clock (TCAPCLK). A programmable prescaler of 1, 2, 3, 4 then divides the selected source.

The Timer Capture clock (TCAPCLK) can be sourced from the Internal 24 MHz Oscillator, or the Internal 32 kHz Low power Oscillator except when in sleep mode.

The CLKOUT pin (P0.1) can be driven from one of many sources. This is used for test and can also be used in some applications.

The sources that can drive the CLKOUT are:

■ CLKIN after the optional EFTB filter

■ Internal 24 MHz Oscillator

■ Internal 32 kHz Low power Oscillator except when in sleep mode

■ CPUCLK after the programmable divider

Table 33. IOSC Trim (IOSCTR) [0x34] [R/W]

Bit #	7	6	5	4	3	2	1	0
Field	foffset[2:0]			Gain[4:0]				
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Default	0	0	0	D	D	D	D	D

The I/OSC Calibrate register is used to calibrate the internal oscillator. The reset value is undefined, but during boot the SROM writes a calibration value that is determined during manufacturing test. This value should not require change during normal use. This is the meaning of 'D' in the Default field

Bits 7:5 foffset [2:0]

This value is used to trim the frequency of the internal oscillator. These bits are not used in factory calibration and is zero. Setting each of these bits causes the appropriate fine offset in oscillator frequency

foffset bit 0 = 7.5 KHz

foffset bit 1 = 15 KHz

foffset bit 2 = 30 KHz

Bits 4:0 Gain [4:0]

The effective frequency change of the offset input is controlled through the gain input. A lower value of the gain setting increases the gain of the offset input. This value sets the size of each offset step for the internal oscillator. Nominal gain change (KHz/off-setStep) at each bit, typical conditions (24 MHz operation):

Gain bit 0 = −1.5 KHz

Gain bit 1 = −3.0 KHz

Gain bit 2 = −6 KHz

Gain bit 3 = −12 KHz

Gain bit 4 = −24 KHz

Table 34. LPOSC Trim (LPOSCTR) [0x36] [R/W]

Bit #	7	6	5	4	3	2	1	0
Field	32 kHz Low Power	Reserved	32 kHz Bias Trim [1:0]		32 kHz Freq Trim [3:0]			
Read/Write	R/W	–	R/W	R/W	R/W	R/W	R/W	R/W
Default	0	D	D	D	D	D	D	D

This register is used to calibrate the 32 kHz Low speed Oscillator. The reset value is undefined, but during boot the SROM writes a calibration value that is determined during manufacturing test. This value should not require change during normal use. This is the meaning of 'D' in the Default field. If the 32 kHz Low power bit needs to be written, care should be taken not to disturb the 32 kHz Bias Trim and the 32 kHz Freq Trim fields from their factory calibrated values

Bit 7 32 kHz Low Power

0 = The 32 kHz Low speed Oscillator operates in normal mode

1 = The 32 kHz Low speed Oscillator operates in a low power mode. The oscillator continues to function normally but with reduced accuracy

Bit 6 Reserved

Bits 5:4 32 kHz Bias Trim [1:0]

These bits control the bias current of the low power oscillator.

0 0 = Mid bias

0 1 = High bias

1 0 = Reserved

1 1 = Reserved

Important Note Do not program the 32 kHz Bias Trim [1:0] field with the reserved 10b value, as the oscillator does not oscillate at all corner conditions with this setting

Bits 3:0 32 kHz Freq Trim [3:0]

These bits are used to trim the frequency of the low power oscillator

Table 35. CPU/USB Clock Config CPUCLKCR) [0x30] [R/W]

Bit #	7	6	5	4	3	2	1	0
Field	Reserved							
Read/Write	–	R/W	R/W	–	–	–	–	R/W
Default	0	0	0	0	0	0	0	0

Bit 7   Reserved

Bit 6   Reserved

Bit 5   Reserved

Bits 4:1   Reserved

Bit 0   Reserved

Note The CPU speed selection is configured using the OSC_CR0 Register (Table 36)

Table 36. OSC Control 0 (OSC_CR0) [0x1E0] [R/W]

Bit #	7	6	5	4	3	2	1	0
Field	Reserved		No Buzz	Sleep Timer [1:0]		CPU Speed [2:0]		
Read/Write	–	–	R/W	R/W	R/W	R/W	R/W	R/W
Default	0	0	0	0	0	0	0	0

Table 36. OSC Control 0 (OSC_CR0) [0x1E0] [R/W] (continued)

Bits 7:6   Reserved

Bit 5   No Buzz

During sleep (the Sleep bit is set in the CPU_SCR Register—Table 40), the POR detection circuit is turned on periodically to de-tect any POR events on the V_{CC} pin (the Sleep Duty Cycle bits in the ECO_TR are used to control the duty cycle—Table 44). To facilitate the detection of POR events, the No Buzz bit is used to force the POR detection circuit to be continuously enabled during sleep. This results in a faster response to a POR event during sleep at the expense of a slightly higher than average sleep current
0 = The POR detection circuit is turned on periodically as configured in the Sleep Duty Cycle
1 = The Sleep Duty Cycle value is overridden. The POR detection circuit is always enabled

Note The periodic Sleep Duty Cycle enabling is independent with the sleep interval shown in the Sleep [1:0] bits below

Bits 4:3   Sleep Timer [1:0]

Sleep Timer [1:0]	Sleep Timer Clock Frequency (Nominal)	Sleep Period (Nominal)	Watchdog Period (Nominal)
00	512 Hz	1.95 ms	6 ms
01	64 Hz	15.6 ms	47 ms
10	8 Hz	125 ms	375 ms
11	1 Hz	1 sec	3 sec

Note Sleep intervals are approximate

Bits 2:0   CPU Speed [2:0]

The CYRF69313 may operate over a range of CPU clock speeds. The reset value for the CPU Speed bits is zero; therefore, the default CPU speed is one-eighth of the internal 24 MHz, or 3 MHz
Regardless of the CPU Speed bit's setting, if the actual CPU speed is greater than 12 MHz, the 24 MHz operating requirements apply. The operating voltage requirements are not relaxed until the CPU speed is at 12 MHz or less

CPU Speed [2:0]	CPU
000	3 MHz (Default)
001	6 MHz
010	12 MHz
011	24 MHz
100	1.5 MHz
101	750 kHz
110	187 kHz
111	Reserved

Important Note Correct USB operations require the CPU clock speed be at least 1.5 MHz or not less than USB clock/8. If the two clocks have the same source then the CPU clock divider should not be set to divide by more than 8. If the two clocks have different sources, care must be taken to ensure that the maximum ratio of USB Clock/CPU Clock can never exceed 8 across the full specifi-cation range of both clock sources

Table 37. USB Osclock Clock Configuration (OSCLCKCR) [0x39] [R/W]

Bit #	7	6	5	4	3	2	1	0
Field	Reserved						Fine Tune Only	USB Osclock Disable
Read/Write	–	–	–	–	–	–	R/W	R/W
Default	0	0	0	0	0	0	0	0

This register is used to trim the Internal 24 MHz Oscillator using received low speed USB packets as a timing reference. The USB Osclock circuit is active when the Internal 24 MHz Oscillator provides the USB clock

Bits 7:2   Reserved

Bit 1   Fine Tune Only

   0 = Enable

   1 = Disable the oscillator lock from performing the course-tune portion of its retuning. The oscillator lock must be allowed to perform a course tuning to tune the oscillator for correct USB SIE operation. After the oscillator is properly tuned this bit can be set to reduce variance in the internal oscillator frequency that would be caused by course tuning

Bit 0   USB Osclock Disable

   0 = Enable. With the presence of USB traffic, the Internal 24 MHz Oscillator precisely tunes to 24 MHz ± 1.5%

   1 = Disable. The Internal 24 MHz Oscillator is not trimmed based on USB packets. This setting is useful when the internal oscillator is not sourcing the USBSIE clock

Table 38. Timer Clock Config (TMRCLKCR) [0x31] [R/W]

Bit #	7	6	5	4	3	2	1	0
Field	TCAPCL Divider		TCAPCLK Select		ITMRCLK Divider		ITMRCLK Select	
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Default	-	-	-	-	1	1	0	0

Bits 7:6   TCAPCLK Divider

   TCAPCLK Divider controls the TCAPCLK divisor

   00 = Divide by 2

   01 = Divide by 4

   10 = Divide by 6

   11 = Divide by 8

Bits 5:4   TCAPCLK Select

   The TCAPCLK Select field controls the source of the TCAPCLK

   0 0 = Internal 24 MHz Oscillator

   0 1 = Reserved)

   1 0 = Internal 32 kHz Low power Oscillator. However this configuration is not used in sleep mode.

   1 1 = TCAPCLK Disabled

Note The 1024-μs interval timer is based on the assumption that TCAPCLK is running at 4 MHz. Changes in TCAPCLK frequency causes a corresponding change in the 1024 μs interval timer frequency

Bits 3:2   ITMRCLK Divider

   ITMRCLK Divider controls the ITMRCLK divisor.

   0 0 = Divider value of 1

   0 1 = Divider value of 2

   1 0 = Divider value of 3

   1 1 = Divider value of 4

Bits 1:0   ITMRCLK Select

   0 0 = Internal 24 MHz Oscillator

   0 1 = Reserved

   1 0 = Internal 32 kHz Low power Oscillator. However this configuration is not used in sleep mode.

   1 1 = TCAPCLK

Interval Timer Clock (ITMRCLK)

The Interval Timer Clock (ITMRCLK) can be sourced from the Internal 24 MHz oscillator, the internal 32 kHz low power oscillator except when in sleep mode, or the timer capture clock. A programmable prescaler of 1, 2, 3, or 4 then divides the selected source. The 12-bit Programmable Interval Timer is a simple down counter with a programmable reload value. It provides a 1 μs resolution by default. When the down counter reaches zero, the next clock is spent reloading. The reload value can be read and written while the counter is running, but care should be taken to ensure that the counter does not unintentionally reload while the 12-bit reload value is only partially stored—for example, between the two writes of the 12-bit value. The programmable interval timer generates an interrupt to the CPU on each reload.

The parameters to be set appears on the device editor view of PSoC Designer after you place the CYRF69313 Timer User Module. The parameters are PITIMER_Source and PITIMER_Divider. The PITIMER_Source is the clock to the timer and the PITMER_Divider is the value the clock is divided by.

The interval register (PITMR) holds the value that is loaded into the PIT counter on terminal count. The PIT counter is a down counter.

The Programmable Interval Timer resolution is configurable. For example:

TCAPCLK divide by x of CPU clock (for example TCAPCLK divide by 2 of a 24 MHz CPU clock gives a frequency of 12 MHz)

ITMRCLK divide by x of TCAPCLK (for example, ITMRCLK divide by 3 of TCAPCLK is 4 MHz so resolution is 0.25 μs)

Timer Capture Clock (TCAPCLK)

The Timer Capture clock can be sourced from the internal 24 MHz oscillator or the Internal 332 kHz low power oscillator except when in sleep mode. A programmable prescaler of 2, 4, 6, or 8 then divides the selected source.

Figure 9. Programmable Interval Timer Block Diagram
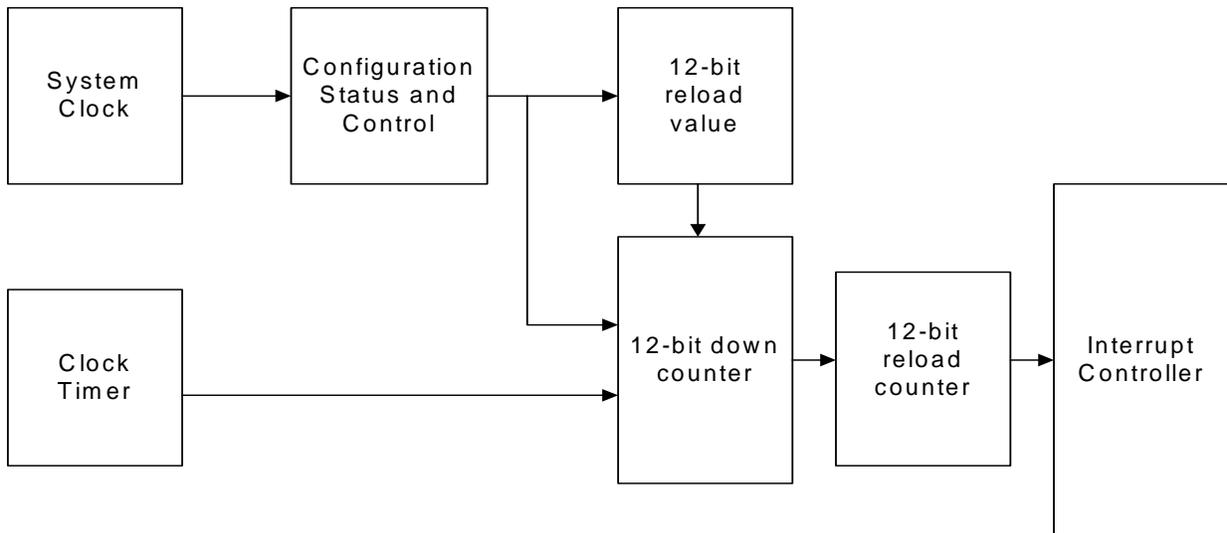

Figure 10. Timer Capture Block Diagram
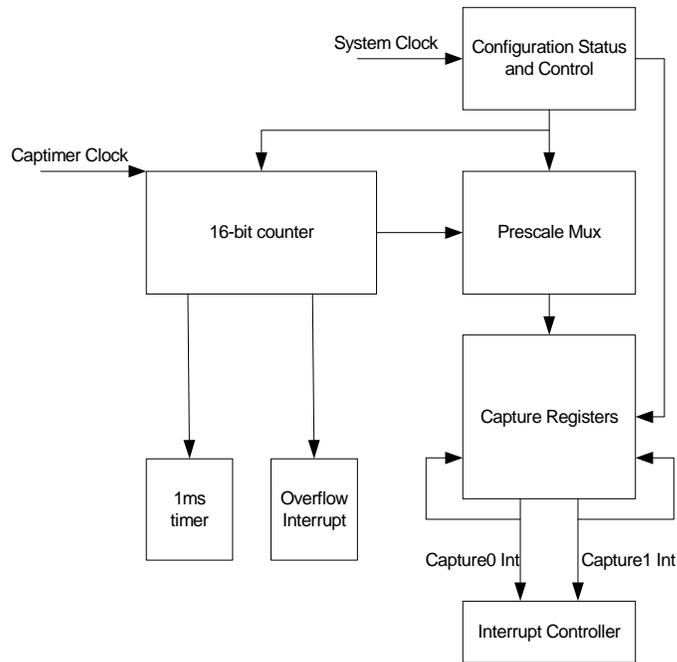

Table 39. Clock I/O Config (CLKIOCR) [0x32] [R/W]

Bit #	7	6	5	4	3	2	1	0
Field	Reserved						CLKOUT Select	
Read/Write	–	–	–	-	-	-	R/W	R/W
Default	0	0	0	0	0	0	0	0

Bits 7:2 Reserved

Bits 1:0   CLKOUT Select

0 0 = Internal 24 MHz Oscillator

0 1 = Reserved

1 0 = Internal 32 kHz Low power Oscillator.However this configuration is not used in sleep mode.

1 1 = CPUCLK

CPU Clock During Sleep Mode

When the CPU enters sleep mode the CPUCLK Select (Bit [0], Table 35) is forced to the internal oscillator, and the oscillator is stopped. When the CPU comes out of sleep mode it is running on the internal oscillator. The internal oscillator recovery time is three clock cycles of the Internal 32 kHz Low power Oscillator.

Reset

The microcontroller supports two types of resets: Power on Reset (POR) and Watchdog Reset (WDR). When reset is initiated, all registers are restored to their default states and all interrupts are disabled.

The occurrence of a reset is recorded in the System Status and Control Register (CPU_SCR). Bits within this register record the occurrence of POR and WDR Reset respectively. The firmware can interrogate these bits to determine the cause of a reset.

The microcontroller resumes execution from Flash address 0x0000 after a reset. The internal clocking mode is active after a reset.

Note The CPU clock defaults to 3 MHz (Internal 24 MHz Oscillator divide-by-8 mode) at POR to guarantee operation at the low V_{CC} that might be present during the supply ramp.

Table 40. System Status and Control Register (CPU_SCR) [0xFF] [R/W]

Bit #	7	6	5	4	3	2	1	0
Field	GIES	Reserved	WDRS	PORS	Sleep	Reserved		Stop
Read/Write	R	–	R/C[3]	R/C[3]	R/W	–	–	R/W
Default	0	0	0	1	0	0	0	0

The bits of the CPU_SCR register are used to convey status and control of events for various functions of an CYRF69313 device

Bit 7   GIES

The Global Interrupt Enable Status bit is a read only status bit and its use is discouraged. The GIES bit is a legacy bit, which was used to provide the ability to read the GIE bit of the CPU_F register. However, the CPU_F register is now readable. When this bit is set, it indicates that the GIE bit in the CPU_F register is also set which, in turn, indicates that the microprocessor services interrupts

0 = Global interrupts disabled

1 = Global interrupt enabled

Bit 6   Reserved

Bit 5   WDRS

The WDRS bit is set by the CPU to indicate that a WDR event has occurred. The user can read this bit to determine the type of reset that has occurred. The user can clear but not set this bit

0 = No WDR

1 = A WDR event has occurred

Bit 4   PORS

The PORS bit is set by the CPU to indicate that a POR event has occurred. The user can read this bit to determine the type of reset that has occurred. The user can clear but not set this bit

0 = No POR

1 = A POR event has occurred. (Note that WDR events does not occur until this bit is cleared)

Bit 3   SLEEP

Set by the user to enable CPU sleep state. CPU remains in sleep mode until any interrupt is pending. The Sleep bit is covered in more detail in the Sleep Mode section

0 = Normal operation

1 = Sleep

Bit 2:1   Reserved

Bit 0   STOP

This bit is set by the user to halt the CPU. The CPU remains halted until a reset (WDR, POR, or external reset) has taken place. If an application wants to stop code execution until a reset, the preferred method would be to use the HALT instruction rather than writing to this bit

0 = Normal CPU operation

1 = CPU is halted (not recommended)

Note
3. C = Clear. This bit can only be cleared by the user and cannot be set by firmware

Power-on Reset

POR occurs every time the power to the device is switched on. POR is released when the supply is typically 2.6 V for the upward supply transition, with typically 50 mV of hysteresis during the power on transient. Bit 4 of the System Status and Control Register (CPU_SCR) is set to record this event (the register contents are set to 00010000 by the POR). After a POR, the microprocessor is held off for approximately 20 ms for the V_{CC} supply to stabilize before executing the first instruction at address 0x00 in the Flash. If the V_{CC} voltage drops below the POR downward supply trip point, POR is reasserted. The V_{CC} supply needs to ramp linearly from 0 to 4 V in 0 to 200 ms.

Important The PORS status bit is set at POR and can only be cleared by the user. It cannot be set by firmware.

Watchdog Timer Reset

The user has the option to enable the WDT. The WDT is enabled by clearing the PORS bit. When the PORS bit is cleared, the WDT cannot be disabled. The only exception to this is if a POR event takes place, which disables the WDT.

The sleep timer is used to generate the sleep time period and the Watchdog time period. The sleep timer is clocked by the Internal 32 kHz Low power Oscillator system clock. The user can program the sleep time period using the Sleep Timer bits of the OSC_CR0 Register (Table 36). When the sleep time elapses (sleep timer overflows), an interrupt to the Sleep Timer Interrupt Vector is generated.

The Watchdog Timer period is automatically set to be three counts of the Sleep Timer overflows. This represents between two and three sleep intervals depending on the count in the Sleep Timer at the previous WDT clear. When this timer reaches three, a WDR is generated.

The user can either clear the WDT, or the WDT and the Sleep Timer. Whenever the user writes to the Reset WDT Register (RES_WDT), the WDT is cleared. If the data that is written is the hex value 0x38, the Sleep Timer is also cleared at the same time.

Table 41. Reset Watchdog Timer (RESWDT) [0xE3] [W]

Bit #	7	6	5	4	3	2	1	0
Field	Reset Watchdog Timer [7:0]							
Read/Write	W	W	W	W	W	W	W	W
Default	0	0	0	0	0	0	0	0

Any write to this register clears Watchdog Timer, a write of 0x38 also clears the Sleep Timer

Bits 7:0 Reset Watchdog Timer [7:0]

Sleep Mode

The CPU can only be put to sleep by the firmware. This is accomplished by setting the Sleep bit in the System Status and Control Register (CPU_SCR). This stops the CPU from executing instructions, and the CPU remains asleep until an interrupt comes pending, or there is a reset event (either a Power on Reset, or a Watchdog Timer Reset).

The internal 32 kHz low speed oscillator remains running. Prior to entering suspend mode, firmware can optionally configure the 32 kHz Low speed Oscillator to operate in a low power mode to help reduce the overall power consumption (using Bit 7, Table 34). This helps save approximately 5 μA; however, the trade off is that the 32 kHz Low speed Oscillator is less accurate.

All interrupts remain active. Only the occurrence of an interrupt wakes the part from sleep. The Stop bit in the System Status and Control Register (CPU_SCR) must be cleared for a part to resume out of sleep. The Global Interrupt Enable bit of the CPU Flags Register (CPU_F) does not have any effect. Any unmasked interrupt wakes the system up. As a result, any interrupts not intended for waking must be disabled through the Interrupt Mask Registers.

When the CPU exits sleep mode the CPUCLK Select (Bit 1, Table 35) is forced to the Internal Oscillator. The internal oscillator recovery time is three clock cycles of the Internal 32 kHz Low power Oscillator. The Internal 24 MHz Oscillator restarts immediately on exiting Sleep mode.

On exiting sleep mode, when the clock is stable and the delay time has expired, the instruction immediately following the sleep instruction is executed before the interrupt service routine (if enabled).

The Sleep interrupt allows the microcontroller to wake up periodically and poll system components while maintaining very low average power consumption. The Sleep interrupt may also be used to provide periodic interrupts during non sleep modes.

Sleep Sequence

The SLEEP bit is an input into the sleep logic circuit. This circuit is designed to sequence the device into and out of the hardware sleep state. The hardware sequence to put the device to sleep is shown in Figure 11 and is defined as follows.

1. Firmware sets the SLEEP bit in the CPU_SCR0 register. The Bus Request (BRQ) signal to the CPU is immediately asserted. This is a request by the system to halt CPU operation at an instruction boundary. The CPU samples BRQ on the positive edge of CPUCLK.

2. Due to the specific timing of the register write, the CPU issues a Bus Request Acknowledge (BRA) on the following positive edge of the CPU clock. The sleep logic waits for the following negative edge of the CPU clock and then asserts a system-wide Power-down (PD) signal. In Figure 11 the CPU is halted and the system-wide power-down signal is asserted.

3. The system-wide PD (power-down) signal controls several major circuit blocks: The Flash memory module, the internal 24 MHz oscillator, the EFTB filter and the bandgap voltage

reference. These circuits transition into a zero power state. The only operational circuits on chip are the low power oscillator, the bandgap refresh circuit, and the supply voltage monitor (POR) circuit.

Note To achieve the lowest possible power consumption during suspend/sleep, the following conditions must be observed in addition to considerations for the sleep timer.

- All GPIOs must be set to outputs and driven low

- The USB pins P1.0 and P1.1 should be configured as inputs with their pull-ups enabled.

Figure 11. Sleep Timing
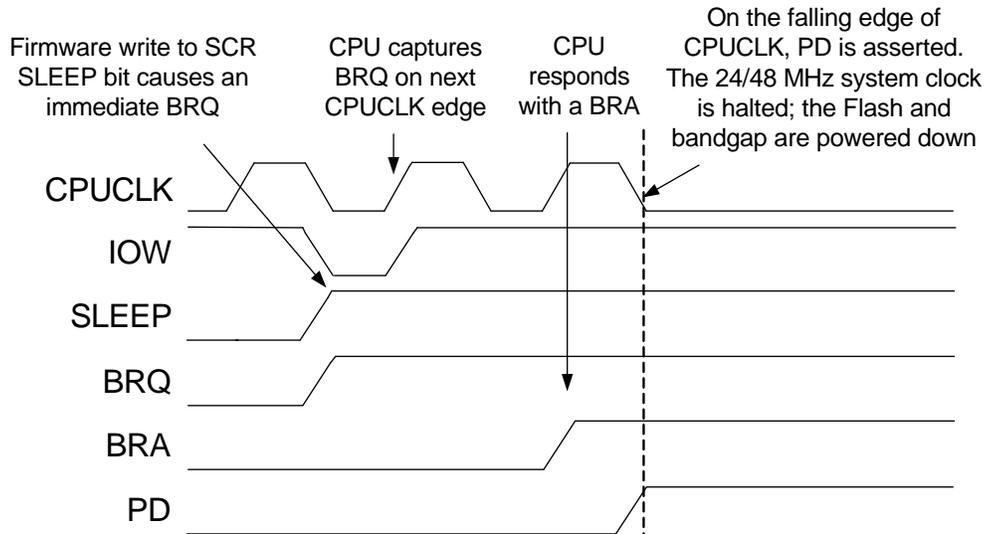

Wakeup Sequence

When asleep, the only event that can wake the system up is an interrupt. The global interrupt enable of the CPU flag register does not need to be set. Any unmasked interrupt wakes the system up. It is optional for the CPU to actually take the interrupt after the wakeup sequence. The wakeup sequence is synchronized to the 32 kHz clock for purposes of sequencing a startup delay, to allow the Flash memory module enough time to power-up before the CPU asserts the first read access. Another reason for the delay is to allow the oscillator, Bandgap, and POR circuits time to settle before actually being used in the system. As shown in Figure 12, the wakeup sequence is as follows:

1. The wakeup interrupt occurs and is synchronized by the negative edge of the 32 kHz clock.

2. At the following positive edge of the 32 kHz clock, the system-wide PD signal is negated. The Flash memory module, internal oscillator, EFTB, and bandgap circuit are all powered up to a normal operating state.

3. At the following positive edge of the 32 kHz clock, the current values for the precision POR have settled and are sampled.

4. At the following negative edge of the 32 kHz clock (after about 15 μs nominal), the BRQ signal is negated by the sleep logic circuit. On the following CPUCLK, BRA is negated by the CPU and instruction execution resumes. Note that in Figure 12 fixed function blocks, such as Flash, internal oscillator, EFTB, and bandgap, have about 15 μs start up. The wakeup times (interrupt to CPU operational) ranges from 75 μs to 105 μs.

Low Power in Sleep Mode

The following steps are mandatory before configuring the system into suspend mode to meet the specifications:

1. Clear P11CR[0], P10CR[0] - during USB and Non-USB operations

2. Clear the USB Enable USBCR[7] - during USB mode operations

3. Set P10CR[1] - during non-USB mode operations

4. To avoid current consumption make sure ITMRCLK, TCPCLK, and USBCLK are not sourced by either low power 32 kHz oscillator or 24 MHz crystal-less oscillator.

All the other blocks go to the power-down mode automatically on suspend.

The following steps are user configurable and help in reducing the average suspend mode power consumption.

1. Configure the power supply monitor at a large regular intervals, control register bits are 1,EB[7:6] (Power system sleep duty cycle PSSDC[1:0]).
2. Configure the low power oscillator into low power mode, control register bit is LOPSCTR[7].

Figure 12. Wakeup Timing
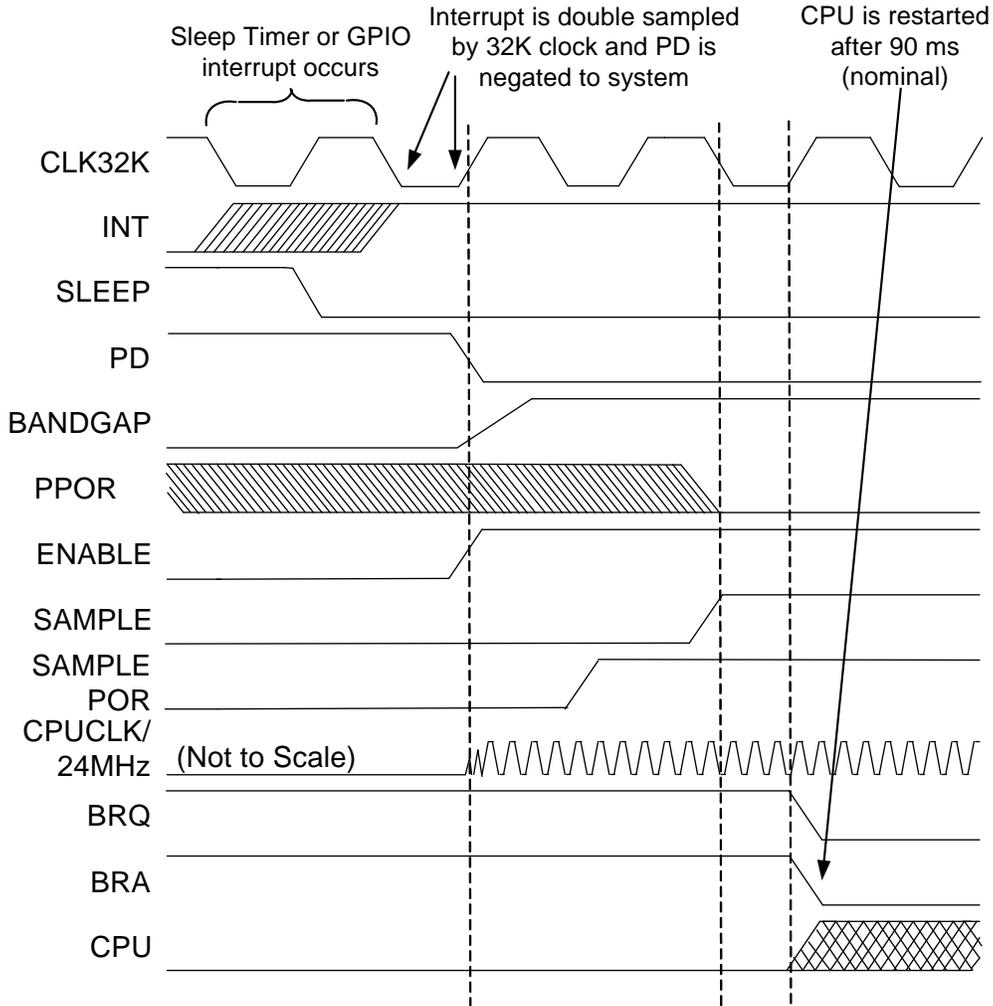

Power-on Reset Control

Table 42. Power On Reset Control Register (POR CR) [0x1E3] [R/W]

Bit #	7	6	5	4	3	2	1	0
Field	Reserved		PORLEV[1:0]		Reserved			
Read/Write	–	–	R/W	R/W	–	–	–	–
Default	0	0	0	0	0	0	0	0

This register controls the configuration of the Power on Reset block

Bits 7:6   Reserved

Bits 5:4   PORLEV[1:0]

    This field controls the level below which the precision power-on-reset (PPOR) detector generates a reset

    0 0 = 2.7 V Range (trip near 2.6 V)

    0 1 = 3 V Range (trip near 2.9 V)

    1 0 = 5 V Range, $\geq$4.75 V (trip near 4.65 V). This setting must be used when operating the CPU above 12 MHz.

    1 1 = PPOR does not generate a reset, but values read from the Voltage Monitor Comparators Register (Table 43) give the internal PPOR comparator state with trip point set to the 3 V range setting

Bits 3:0   Reserved

POR Compare State

Table 43. Voltage Monitor Comparators Register (VLTCMP) [0x1E4] [R]

Bit #	7	6	5	4	3	2	1	0
Field	Reserved							PPOR
Read/Write	–	–	–	–	–	–	–	R
Default	0	0	0	0	0	0	0	0

This read-only register allows reading the current state of the Precision-Power-On-Reset comparators

Bits 7:1   Reserved

Bit 0   PPOR

    This bit is set to indicate that the precision-power-on-reset comparator has tripped, indicating that the supply voltage is below the trip point set by PORLEV[1:0]

    0 = No precision-power-on-reset event

    1 = A precision-power-on-reset event has tripped

ECO Trim Register

Table 44. ECO (ECO_TR) [0x1EB] [R/W]

Bit #	7	6	5	4	3	2	1	0
Field	Sleep Duty Cycle [1:0]		Reserved					
Read/Write	R/W	R/W	–	–	–	–	–	–
Default	0	0	0	0	0	0	0	0

This register controls the ratios (in numbers of 32 kHz clock periods) of 'on' time versus 'off' time for POR detection circuit

Bits 7:6   Sleep Duty Cycle [1:0]

    0 0 = 1/128 periods of the Internal 32 kHz Low speed Oscillator

    0 1 = 1/512 periods of the Internal 32 kHz Low speed Oscillator

    1 0 = 1/32 periods of the Internal 32 kHz Low speed Oscillator

    1 1 = 1/8 periods of the Internal 32 kHz Low speed Oscillator

General-Purpose I/O Ports

The general purpose I/O ports are discussed in the following sections.

Port Data Registers

Table 45. P0 Data Register (P0DATA)[0x00] [R/W]

Bit #	7	6	5	4	3	2	1	0
Field	P0.7	Reserved	Reserved	P0.4/INT2	P0.3/INT1	Reserved	P0.1	Reserved
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Default	0	0	0	0	0	0	0	0

This register contains the data for Port 0. Writing to this register sets the bit values to be output on output enabled pins. Reading from this register returns the current state of the Port 0 pins

Bit 7   P0.7 Data

Bits 6:5   Reserved

   The use of the pins as the P0.6–P0.5 GPIOs and the alternative functions exist in the CYRF69313

Bits 4:3   P0.4–P0.3 Data/INT2 – INT1

   In addition to their use as the P0.4–P0.3 GPIOs, these pins can also be used for the alternative functions as the Interrupt pins (INT0–INT2). To configure the P0.4–P0.3 pins, refer to the P0.3/INT1–P0.4/INT2 Configuration Register (Table 49)

   The use of the pins as the P0.4–P0.3 GPIOs and the alternative functions exist in the CYRF69313

Bit 2   Reserved

Bit 1   P0.1

Bit 0   Reserved

Table 46. P1 Data Register (P1DATA) [0x01] [R/W]

Bit #	7	6	5	4	3	2	1	0
Field	P1.7	P1.6/SMISO	P1.5/SMOSI	P1.4/SCLK	P1.3/SSEL	P1.2	P1.1/D–	P1.0/D+
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Default	0	0	0	0	0	0	0	0

This register contains the data for Port 1. Writing to this register sets the bit values to be output on output enabled pins. Reading from this register returns the current state of the Port 1 pins

Bit 7   P1.7 Data

Bits 6:3   P1.6–P1.3 Data/SPI Pins (SMISO, SMOSI, SCLK, SSEL)

   In addition to their use as the P1.6–P1.3 GPIOs, these pins can also be used for the alternative function as the SPI interface pins. To configure the P1.6–P1.3 pins, refer to the P1.3–P1.6 Configuration Register (Table 54)

   The use of the pins as the P1.6–P1.3 GPIOs and the alternative functions exist in all the CYRF69313 parts

Bit 2   P1.2

   This pin is used as the regulator output.

Bits 1:0   P1.1–P1.0/D– and D+

   When USB mode is disabled (Bit 7 in Table 78 is clear), the P1.1 and P1.0 bits are used to control the state of the P1.0 and P1.1 pins. When the USB mode is enabled, the P1.1 and P1.0 pins are used as the D– and D+ pins, respectively. If the USB Force State bit (Bit 0 in Table 77) is set, the state of the D– and D+ pins can be controlled by writing to the D– and D+ bits

Table 47. P2 Data Register (P2DATA) [0x02] [R/W]

Bit #	7	6	5	4	3	2	1	0
Field	Reserved						P2.1–P2.0	
Read/Write	-	-	-	-	-	-	R/W	R/W
Default	0	0	0	0	0	0	0	0

This register contains the data for Port 2. Writing to this register sets the bit values to be output on output enabled pins. Reading from this register returns the current state of the Port 2 pins

Bits 7:2   Reserved Data [7:2]

Bits 1:0   P2 Data [1:0]

GPIO Port Configuration

All the GPIO configuration registers have common configuration controls. The following are the bit definitions of the GPIO configuration registers.

Int Enable

When set, the Int Enable bit allows the GPIO to generate interrupts. Interrupt generate can occur regardless of whether the pin is configured for input or output. All interrupts are edge sensitive, however for any interrupt that is shared by multiple sources (that is, Ports 2, 3, and 4) all inputs must be deasserted before a new interrupt can occur.

When clear, the corresponding interrupt is disabled on the pin.

It is possible to configure GPIOs as outputs, enable the interrupt on the pin and then to generate the interrupt by driving the appropriate pin state. This is useful in test and may have value in applications as well.

Int Act Low

When set, the corresponding interrupt is active on the falling edge.

When clear, the corresponding interrupt is active on the rising edge.

TTL Thresh

When set, the input has TTL threshold. When clear, the input has standard CMOS threshold.

High Sink

When set, the output can sink up to 50 mA.

When clear, the output can sink up to 8 mA.

On the CYRF69313, only the P1.7–P1.3 have 50 mA sink drive capability. Other pins have 8 mA sink drive capability.

Open Drain

When set, the output on the pin is determined by the Port Data Register. If the corresponding bit in the Port Data Register is set, the pin is in high impedance state. If the corresponding bit in the Port Data Register is clear, the pin is driven low.

When clear, the output is driven LOW or HIGH.

Pull-up Enable

When set the pin has a 7 K pull-up to V_{CC}.

When clear, the pull-up is disabled.

Output Enable

When set, the output driver of the pin is enabled.

When clear, the output driver of the pin is disabled.

For pins with shared functions there are some special cases.

SPI Use

The P1.3 (SSEL), P1.4 (SCLK), P1.5 (SMOSI) and P1.6 (SMISO) pins can be used for their dedicated functions or for GPIO.

The SPI function controls the output enable for its dedicated function pins when their GPIO enable bit is clear.

3.3 V Drive

The P1.3 (SSEL), P1.4 (SCLK), P1.5 (SMOSI) and P1.6 (SMISO) pins have an alternate voltage source from the voltage regulator. If the 3.3 V Drive bit is set a high level is driven from the voltage regulator instead of from V_{CC}.

Table 48. P0.1 Configuration (P01CR) [0x06] R/W

Bit #	7	6	5	4	3	2	1	0
Field	Reserved	Int Enable	Int Act Low	TTL Thresh	High Sink	Open Drain	Pull-up Enable	Output Enable
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Default	0	0	0	0	0	0	0	0

This register is used to configure P0.1 In the CYRF69313, only 8 mA sink drive capability is available on this pin regardless of the setting of the High Sink bit

Bit 7: Reserved

Table 49. P0.3/INT1–P0.4/INT2 Configuration (P03CR–P04CR) [0x08–0x09] [R/W]

Bit #	7	6	5	4	3	2	1	0
Field	Reserved		Int Act Low	TTL Thresh	Reserved	Open Drain	Pull-up Enable	Output Enable
Read/Write	–	–	R/W	R/W	–	R/W	R/W	R/W
Default	0	0	0	0	0	0	0	0

These registers control the operation of pins P0.3–P0.4, respectively. These pins are shared between the P0.3–P0.4 GPIOs and the INT0–INT2. These registers exist in all CYRF69313 parts. The INT0–INT2 interrupts are different than all the other GPIO interrupts. These pins are connected directly to the interrupt controller to provide three edge-sensitive interrupts with independent interrupt vectors. These interrupts occur on a rising edge when Int act Low is clear and on a falling edge when Int act Low is set. These pins are enabled as interrupt sources in the interrupt controller registers (Table 75 and Table 73)

To use these pins as interrupt inputs configure them as inputs by clearing the corresponding Output Enable. If the INT0–INT2 pins are configured as outputs with interrupts enabled, firmware can generate an interrupt by writing the appropriate value to the P0.3 and P0.4 data bits in the P0 Data Register

Regardless of whether the pins are used as Interrupt or GPIO pins the Int Enable, Int act Low, TTL Threshold, Open Drain, and Pull-up Enable bits control the behavior of the pin

The P0.3/INT1–P0.4/INT2 pins are individually configured with the P03CR (0x08), and P04CR (0x09), respectively.

Note Changing the state of the Int Act Low bit can cause an unintentional interrupt to be generated. When configuring these interrupt sources, it is best to follow the following procedure:

1. Disable interrupt source

2. Configure interrupt source

3. Clear any pending interrupts from the source

4. Enable interrupt source

Table 50. P0.7 Configuration (P07CR) [0x0C] [R/W]

Bit #	7	6	5	4	3	2	1	0
Field	Reserved	Int Enable	Int Act Low	TTL Thresh	Reserved	Open Drain	Pull-up Enable	Output Enable
Read/Write	–	R/W	R/W	R/W	–	R/W	R/W	R/W
Default	0	0	0	0	0	0	0	0

This register controls the operation of pin P0.7.

Table 51. P1.0/D+ Configuration (P10CR) [0x0D] [R/W]

Bit #	7	6	5	4	3	2	1	0
Field	Reserved	Int Enable	Int Act Low	Reserved			5 K pull-up enable	Output Enable
Read/Write	R/W	R/W	R/W	–	–	–	–	R/W
Default	0	0	0	0	0	0	0	0

This register controls the operation of the P1.0 (D+) pin when the USB interface is not enabled, allowing the pin to be used as a GPIO pin which is pulled up. See Table 78 for information on enabling USB. When USB is enabled, none of the controls in this register have any effect on the P1.0 pin

Note The P1.0 is an open drain only output. It can actively drive a signal low, but cannot actively drive a signal high

Bit 1   5 K Pull-up Enable
    0 = Disable the 5 kΩ pull-up resistors
    1 = Enable 5 kΩ pull-up resistors for both P1.0 and P1.1. Enable the use of the P1.0 (D+) and P1.1 (D–) pins as pulled up GPIOs
Bit 0 This bit enables the output on P1.0/D+. This bit should be cleared in sleep mode.

Table 52. P1.1/D– Configuration (P11CR) [0x0E] [R/W]

Bit #	7	6	5	4	3	2	1	0
Field	Reserved	Int Enable	Int Act Low	Reserved		Open Drain	Reserved	Output En-able
Read/Write	–	R/W	R/W	–	–	R/W	–	R/W
Default	0	0	0	0	0	0	0	0

This register controls the operation of the P1.1 (D–) pin when the USB interface is not enabled, allowing the pin to be used as a GPIO. See Table 78 for information on enabling USB. When USB is enabled, none of the controls in this register have any effect on the P1.1 pin. When USB is disabled, the 5 kΩ pull-up resistor on this pin can be enabled by the 5 K Pull-up Enable bit of the P10CR Register (Table 51)

Bit 0This bit enables the output on P1.1/D-. This bit should be cleared in sleep mode.

Note There is no 2 mA sourcing capability on this pin. The pin can only sink 5 mA at V_{OL3}

Table 53. P1.2 Configuration (P12CR) [0x0F] [R/W]

Bit #	7	6	5	4	3	2	1	0
Field	CLK Output	Int Enable	Int Act Low	TTL Thresh-old	Reserved	Open Drain	Pull-up En-able	Output En-able
Read/Write	R/W	R/W	R/W	R/W	–	R/W	R/W	R/W
Default	0	0	0	0	0	0	0	0

This register controls the operation of the P1.2

Bit 7 CLK Output
   0 = The internally selected clock is not sent out onto P1.2 pin
   1 = When CLK Output is set, the internally selected clock is sent out onto P1.2 pin

Table 54. P1.3 Configuration (P13CR) [0x10] [R/W]

Bit #	7	6	5	4	3	2	1	0
Field	Reserved	Int Enable	Int Act Low	3.3 V Drive	High Sink	Open Drain	Pull-up En-able	Output En-able
Read/Write	–	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Default	0	0	0	0	0	0	0	0

This register controls the operation of the P1.3 pin. This register exists in all CYRF69313 parts

The P1.3 GPIO's threshold is always set to TTL

When the SPI hardware is enabled, the output enable and output state of the pin is controlled by the SPI circuitry. When the SPI hardware is disabled, the pin is controlled by the Output Enable bit and the corresponding bit in the P1 data register

Regardless of whether the pin is used as an SPI or GPIO pin the Int Enable, Int act Low, 3.3 V Drive, High Sink, Open Drain, and Pull-up Enable control the behavior of the pin

The 50 mA sink drive capability is only available in the CY7C638xx.

Table 55. P1.4–P1.6 Configuration (P14CR–P16CR) [0x11–0x13] [R/W]

Bit #	7	6	5	4	3	2	1	0
Field	SPI Use	Int Enable	Int Act Low	3.3 V Drive	High Sink	Open Drain	Pull-up Enable	Output Enable
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Default	0	0	0	0	0	0	0	0

These registers control the operation of pins P1.4–P1.6, respectively

The P1.4–P1.6 GPIO's threshold is always set to TTL

When the SPI hardware is enabled, pins that are configured as SPI Use have their output enable and output state controlled by the SPI circuitry. When the SPI hardware is disabled or a pin has its SPI Use bit clear, the pin is controlled by the Output Enable bit and the corresponding bit in the P1 data register

Regardless of whether any pin is used as an SPI or GPIO pin the Int Enable, Int act Low, 3.3 V Drive, High Sink, Open Drain, and Pull-up Enable control the behavior of the pin

Bit 7   SPI Use

0 = Disable the SPI alternate function. The pin is used as a GPIO

1 = Enable the SPI function. The SPI circuitry controls the output of the pin

Important Note for Comm Modes 01 or 10 (SPI Master or SPI Slave, see Table 59**)**

When configured for SPI (SPI Use = 1 and Comm Modes [1:0] = SPI Master or SPI Slave mode), the input/output direction of pins P1.3, P1.5, and P1.6 is set automatically by the SPI logic. However, pin P1.4's input/output direction is NOT automatically set; it must be explicitly set by firmware. For SPI Master mode, pin P1.4 must be configured as an output; for SPI Slave mode, pin P1.4 must be configured as an input

Table 56. P1.7 Configuration (P17CR) [0x14] [R/W]

Bit #	7	6	5	4	3	2	1	0
Field	Reserved	Int Enable	Int Act Low	TTL Thresh	High Sink	Open Drain	Pull-up Enable	Output Enable
Read/Write	–	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Default	0	0	0	0	0	0	0	0

This register controls the operation of pin P1.7. This register only exists in CY7C638xx

The 50 mA sink drive capability is only available in the CY7C638xx. The P1.7 GPIO's threshold is always set to TTL

Table 57. P2 Configuration (P2CR) [0x15] [R/W]

Bit #	7	6	5	4	3	2	1	0
Field	Reserved	Int Enable	Int Act Low	TTL Thresh	High Sink	Open Drain	Pull-up Enable	Output Enable
Read/Write	–	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Default	0	0	0	0	0	0	0	0

This register only exists in CY7C638xx. This register controls the operation of pins P2.0–P2.1. In the CY7C638xx, only 8 mA sink drive capability is available on this pin regardless of the setting of the High Sink bit

GPIO Configurations for Low Power Mode:

To ensure low power mode, unbonded GPIO pins in CYRF69313 must be placed in a non floating state. The following assembly code snippet shows how this is achieved. This snippet can be added as a part of the initialization routine.

```
//Code Snippet for addressing unbonded GPIOs

mov A, 00h
mov reg[1Fh],A
mov A, 01h
mov reg[16h],A // Port3 Configuration register - Enable ouptut
mov A, 00h
mov reg[03h],A // Asserting P3.0 and P3.1 outputs to '0'
mov A, 01h
mov reg[05h],A // Port0.0 Configuration register - Enable output
mov reg[07h],A // Port0.2 Configuration register - Enable output
mov reg[0Ah],A // Port0.5 Configuration register - Enable output
mov reg[0Bh],A // Port0.6 Configuration register - Enable output
mov A,reg[00h]
mov A,00h
and A,9Ah
mov reg[00h], A // Asserting outputs '0' to pins in port 1
```

When writing to port 0 , to access GPIOs P0.1,3,4,7, mask bits 0,2,5,6. Failing to do so voids the low power

Serial Peripheral Interface (SPI)

The SPI Master/Slave Interface core logic runs on the SPI clock domain, making its functionality independent of system clock speed. SPI is a four pin serial interface comprised of a clock, an enable and two data pins.

Figure 13. SPI Block Diagram
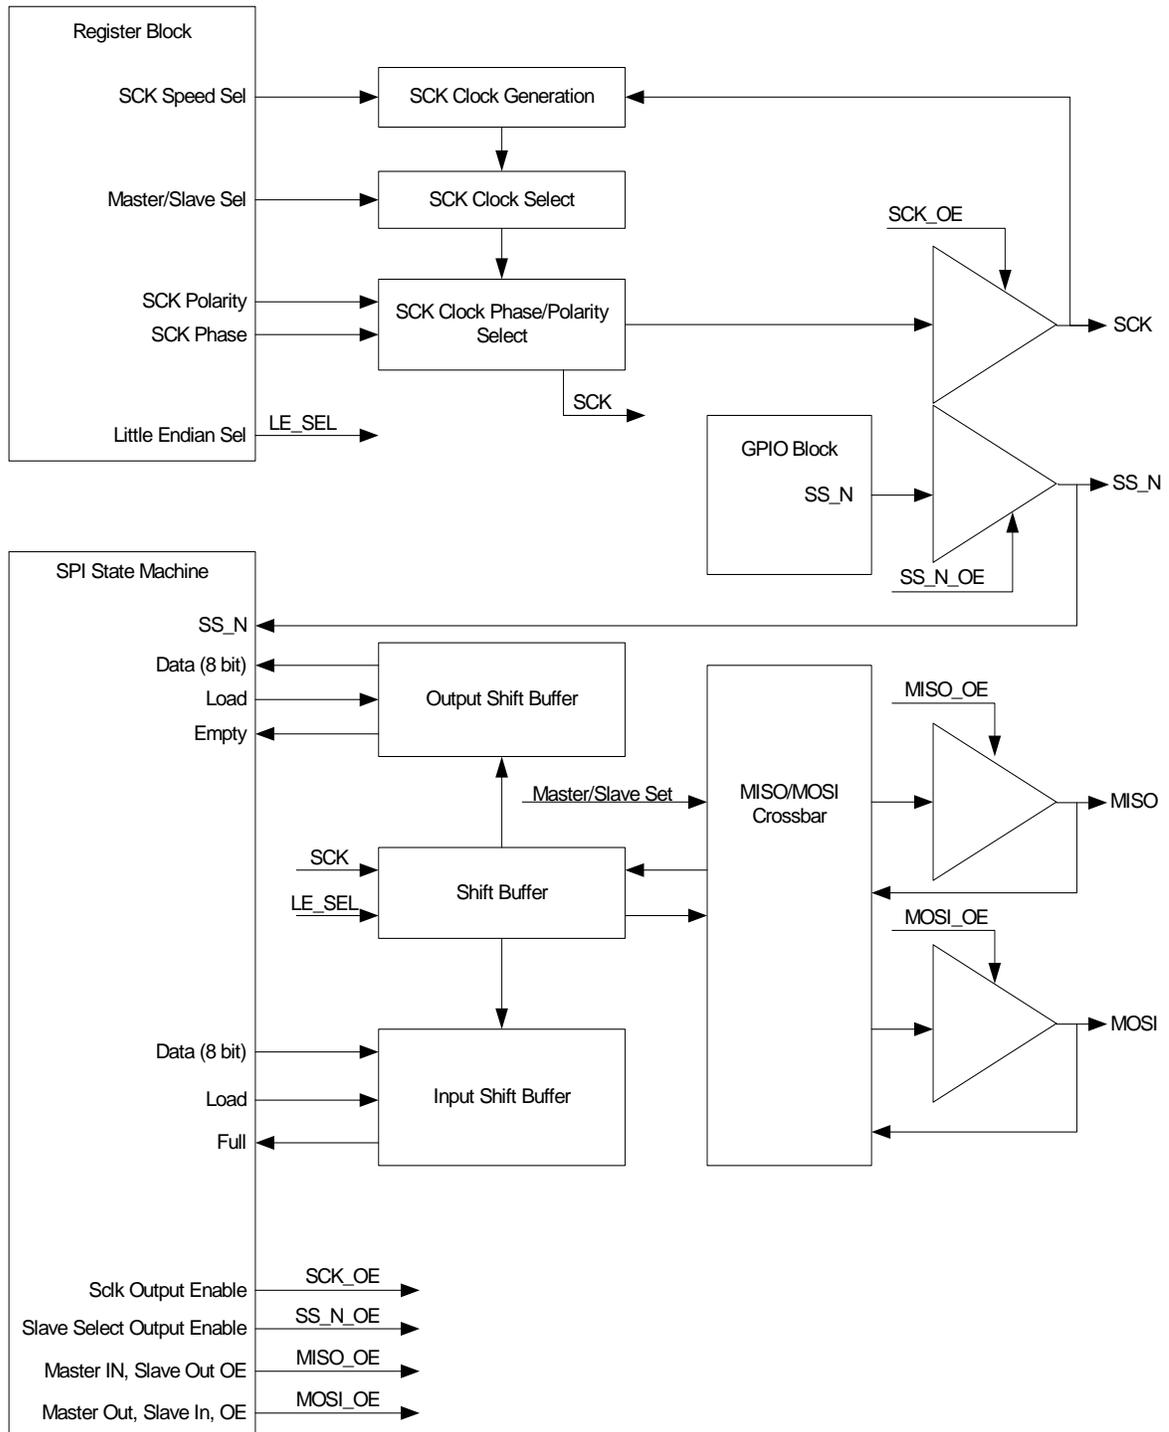

SPI Data Register

Table 58. SPI Data Register (SPIDATA) [0x3C] [R/W]

Bit #	7	6	5	4	3	2	1	0
Field	SPIData[7:0]							
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Default	0	0	0	0	0	0	0	0

When read, this register returns the contents of the receive buffer. When written, it loads the transmit holding register

Bits 7:0   SPI Data [7:0]

When an interrupt occurs to indicate to firmware that a byte of receive data is available, or the transmitter holding register is empty, firmware has 7 SPI clocks to manage the buffers—to empty the receiver buffer, or to refill the transmit holding register. Failure to meet this timing requirement results in incorrect data transfer.

SPI Configure Register

Table 59. SPI Configure Register (SPICR) [0x3D] [R/W]

Bit #	7	6	5	4	3	2	1	0
Field	Swap	LSB First	Comm Mode		CPOL	CPHA	SCLK Select	
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Default	0	0	0	0	0	0	0	0

Bit 7   Swap
   0 = Swap function disabled
   1 = The SPI block swaps its use of SMOSI and SMISO. Among other things, this can be useful in implementing single wire SPI-like communications
Bit 6   LSB First
   0 = The SPI transmits and receives the MSB (Most Significant Bit) first
   1 = The SPI transmits and receives the LSB (Least Significant Bit) first.
Bits 5:4   Comm Mode [1:0]
   0 0: All SPI communication disabled
   0 1: SPI master mode
   1 0: SPI slave mode
   1 1: Reserved
Bit 3   CPOL
   This bit controls the SPI clock (SCLK) idle polarity
   0 = SCLK idles low
   1 = SCLK idles high
Bit 2   CPHA
   The Clock Phase bit controls the phase of the clock on which data is sampled. Table 60 shows the timing for the various combinations of LSB First, CPOL, and CPHA
Bits 1:0   SCLK Select
   This field selects the speed of the master SCLK. When in master mode, SCLK is generated by dividing the base CPUCLK
Important Note for Comm Modes 01b or 10b (SPI Master or SPI Slave):
When configured for SPI, (SPI Use = 1—Table 55), the input/output direction of pins P1.3, P1.5, and P1.6 is set automatically by the SPI logic. However, pin P1.4's input/output direction is NOT automatically set; it must be explicitly set by firmware. For SPI Master mode, pin P1.4 must be configured as an output; for SPI Slave mode, pin P1.4 must be configured as an input

Table 60. SPI Mode Timing vs. LSB First, CPOL and CPHA

LSB First	CPHA	CPOL	Diagram
0	0	0	
0	0	1	
0	1	0	
0	1	1	
1	0	0	
1	0	1	
1	1	0	
1	1	1	
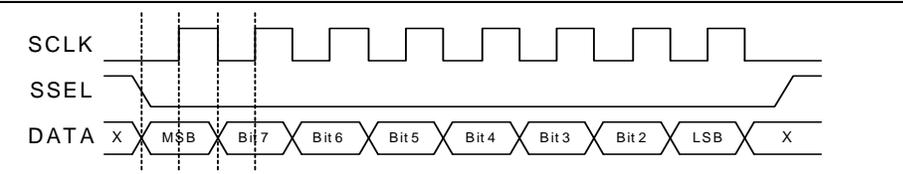

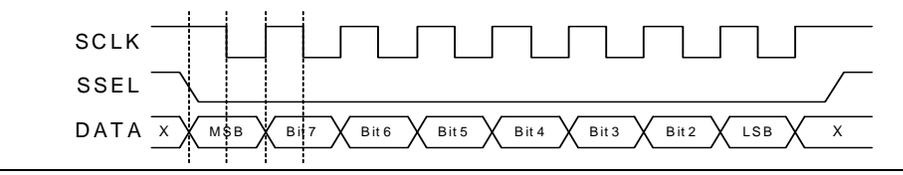

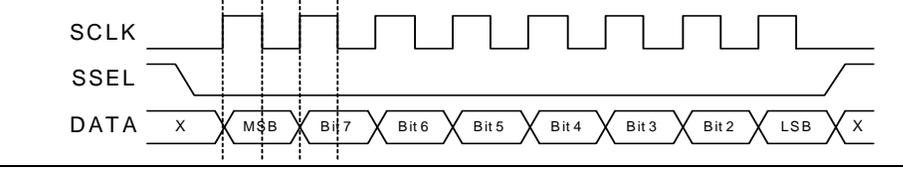

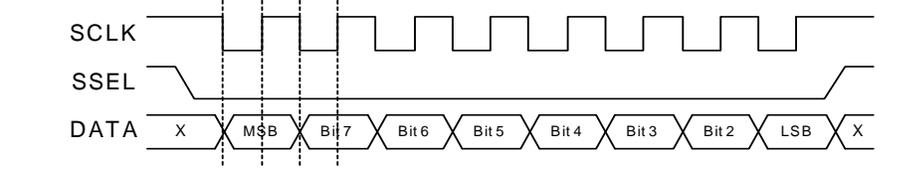

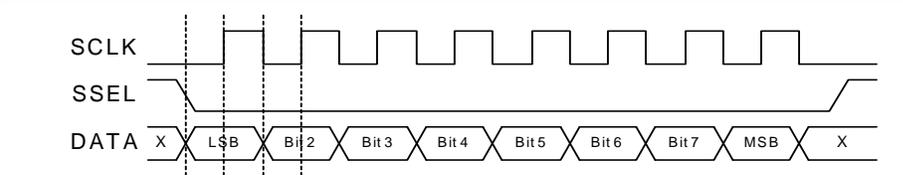

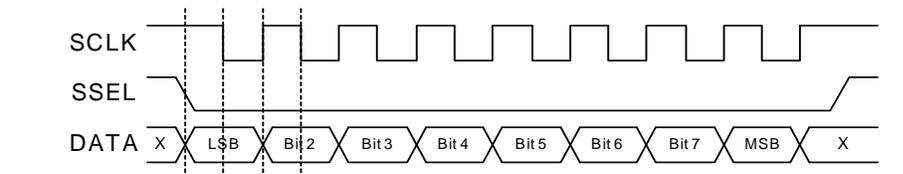

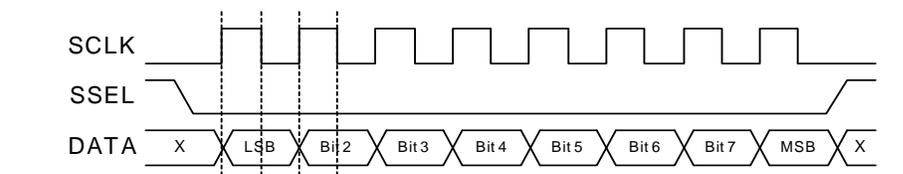

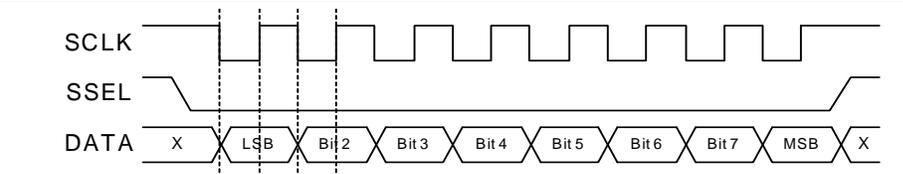

Table 61. SPI SCLK Frequency

SCLK Select	CPUCLK Divisor	SCLK Frequency when CPUCLK =	
		12 MHz	**24 MHz**
00	6	2 MHz	4 MHz
01	12	1 MHz	2 MHz
10	48	250 KHz	500 KHz
11	96	125 KHz	250 KHz

Timer Registers

All timer functions of the CYRF69313 are provided by a single timer block. The timer block is asynchronous from the CPU clock.

Registers

Free-Running Counter

The 16-bit free-running counter is clocked by a 4/6 MHz source. It can be read in software for use as a general purpose time base. When the low order byte is read, the high order byte is registered.

Reading the high order byte reads this register allowing the CPU to read the 16-bit value atomically (loads all bits at one time). The free-running timer generates an interrupt at a 1024 μs rate. It can also generate an interrupt when the free-running counter overflow occurs—every 16.384 ms. This allows extending the length of the timer in software.

Figure 14. 16-Bit Free-Running Counter Block Diagram
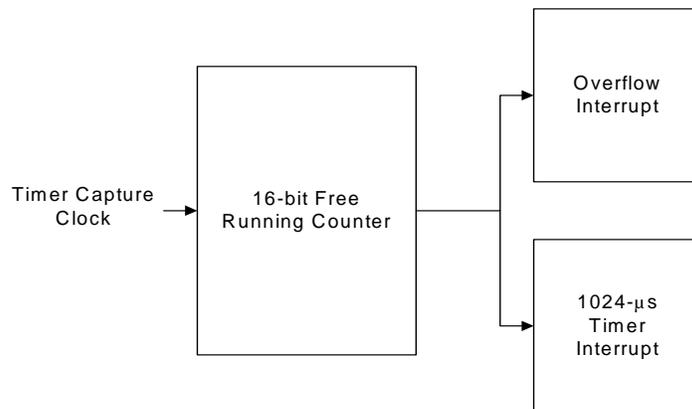

Table 62. Free-Running Timer Low Order Byte (FRTMRL) [0x20] [R/W]

Bit #	7	6	5	4	3	2	1	0
Field	Free-running Timer [7:0]							
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Default	0	0	0	0	0	0	0	0

Bits 7:0 Free-running Timer [7:0]

This register holds the low order byte of the 16-bit free-running timer. Reading this register causes the high order byte to be moved into a holding register allowing an automatic read of all 16 bits simultaneously.

For reads, the actual read occurs in the cycle when the low order is read. For writes, the actual time the write occurs is the cycle when the high order is written

When reading the free-running timer, the low order byte should be read first and the high order second. When writing, the low order byte should be written first then the high order byte

Table 63. Free-Running Timer High Order Byte (FRTMRH) [0x21] [R/W]

Bit #	7	6	5	4	3	2	1	0
Field	Free-running Timer [15:8]							
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Default	0	0	0	0	0	0	0	0

Bits 7:0 Free-running Timer [15:8]

When reading the free-running timer, the low order byte should be read first and the high order second. When writing, the low order byte should be written first then the high order byte

Table 64. Programmable Interval Timer Low (PITMRL) [0x26] [R]

Bit #	7	6	5	4	3	2	1	0
Field	Prog Interval Timer [7:0]							
Read/Write	R	R	R	R	R	R	R	R
Default	0	0	0	0	0	0	0	0

Bits 7:0 'Prog Interval Timer [7:0]

This register holds the low order byte of the 12-bit programmable interval timer. Reading this register causes the high order byte to be moved into a holding register allowing an automatic read of all 12 bits simultaneously

Table 65. Programmable Interval Timer High (PITMRH) [0x27] [R]

Bit #	7	6	5	4	3	2	1	0
Field	Reserved				Prog Interval Timer [11:8]			
Read/Write	–	–	–	–	R	R	R	R
Default	0	0	0	0	0	0	0	0

Bits 7:4   Reserved

Bits 3:0   Prog Internal Timer [11:8]

This register holds the high order nibble of the 12-bit programmable interval timer. Reading this register returns the high order nibble of the 12-bit timer at the instant that the low order byte was last read

Table 66. Programmable Interval Reload Low (PIRL) [0x28] [R/W]

Bit #	7	6	5	4	3	2	1	0
Field	Prog Interval [7:0]							
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Default	0	0	0	0	0	0	0	0

Bits 7:0 Prog Interval [7:0]

This register holds the lower 8 bits of the timer. While writing into the 12-bit reload register, write lower byte first then the higher nibble

Table 67. Programmable Interval Reload High (PIRH) [0x29] [R/W]

Bit #	7	6	5	4	3	2	1	0

Interrupt Controller

The interrupt controller and its associated registers allow the user's code to respond to an interrupt from almost every functional block in the CYRF69313 devices. The registers associated with the interrupt controller allow interrupts to be disabled either globally or individually. The registers also provide a mechanism by which a user may clear all pending and posted interrupts, or clear individual posted or pending interrupts.

The following table lists all interrupts and the priorities that are available in the CYRF69313.

Table 68. Interrupt Numbers, Priorities, Vectors

Interrupt Priority	Interrupt Address	Name
0	0000h	Reset
1	0004h	POR
2	0008h	INT0
3	000Ch	SPI Transmitter Empty
4	0010h	SPI Receiver Full
5	0014h	GPIO Port 0
6	0018h	GPIO Port 1
7	001Ch	INT1
8	0020h	EP0
9	0024h	EP1
10	0028h	EP2
11	002Ch	USB Reset
12	0030h	USB Active
13	0034h	1 ms Interval timer
14	0038h	Programmable Interval Timer
15	003Ch	Reserved
16	0040h	Reserved

Table 68. Interrupt Numbers, Priorities, Vectors (continued)

Interrupt Priority	Interrupt Address	Name
17	0044h	16-bit Free Running Timer Wrap
18	0048h	INT2
19	004Ch	Reserved
20	0050h	GPIO Port 2
21	0054h	Reserved
22	0058h	Reserved
23	005Ch	Reserved
24	0060h	Reserved
25	0064h	Sleep Timer

Architectural Description

An interrupt is posted when its interrupt conditions occur. This results in the flip-flop in Figure 17 clocking in a '1'. The interrupt remains posted until the interrupt is taken or until it is cleared by writing to the appropriate INT_CLRx register.

A posted interrupt is not pending unless it is enabled by setting its interrupt mask bit (in the appropriate INT_MSKx register). All pending interrupts are processed by the Priority Encoder to determine the highest priority interrupt which is taken by the M8C if the Global Interrupt Enable bit is set in the CPU_F register.

Disabling an interrupt by clearing its interrupt mask bit (in the INT_MSKx register) does not clear a posted interrupt, nor does it prevent an interrupt from being posted. It simply prevents a posted interrupt from becoming pending.

Nested interrupts can be accomplished by re-enabling interrupts inside an interrupt service routine. To do this, set the IE bit in the Flag Register.

A block diagram of the CYRF69313 Interrupt Controller is shown in Figure 17.

Figure 17. Interrupt Controller Block Diagram
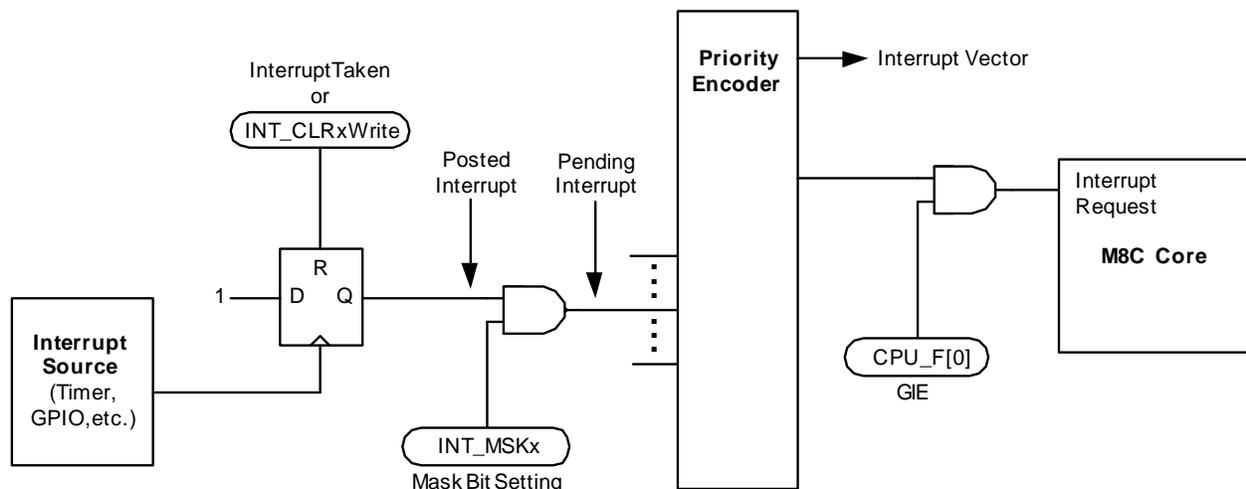

Interrupt Processing

The sequence of events that occur during interrupt processing is as follows:

1. An interrupt becomes active, either because:
   a. The interrupt condition occurs (for example, a timer expires).
   b. A previously posted interrupt is enabled through an update of an interrupt mask register.
   c. An interrupt is pending and GIE is set from 0 to 1 in the CPU Flag register.
   d. The GPIO interrupts are edge triggered.
1. The current executing instruction finishes.
2. The internal interrupt is dispatched, taking 13 cycles. During this time, the following actions occur:
   a. The MSB and LSB of Program Counter and Flag registers (CPU_PC and CPU_F) are stored onto the program stack by an automatic CALL instruction (13 cycles) generated during the interrupt acknowledge process.
   b. The PCH, PCL, and Flag register (CPU_F) are stored onto the program stack (in that order) by an automatic CALL instruction (13 cycles) generated during the interrupt acknowledge process.
   c. The CPU_F register is then cleared. Because this clears the GIE bit to 0, additional interrupts are temporarily disabled
   d. The PCH (PC[15:8]) is cleared to zero.
   e. The interrupt vector is read from the interrupt controller and its value placed into PCL (PC[7:0]). This sets the program counter to point to the appropriate address in the interrupt table (for example, 0004h for the POR interrupt).
1. Program execution vectors to the interrupt table. Typically, a LJMP instruction in the interrupt table sends execution to the user's Interrupt Service Routine (ISR) for this interrupt.
2. The ISR executes. Note that interrupts are disabled because GIE = 0. In the ISR, interrupts can be re-enabled if desired by setting GIE = 1 (care must be taken to avoid stack overflow).

3. The ISR ends with a RETI instruction which restores the Program Counter and Flag registers (CPU_PC and CPU_F). The restored Flag register re-enables interrupts, because GIE = 1 again.
4. Execution resumes at the next instruction, after the one that occurred before the interrupt. However, if there are more pending interrupts, the subsequent interrupts are processed before the next normal program instruction.

Interrupt Latency

The time between the assertion of an enabled interrupt and the start of its ISR can be calculated from the following equation.

Latency = Time for current instruction to finish + Time for internal interrupt routine to execute + Time for LJMP instruction in interrupt table to execute.

For example, if the 5 cycle JMP instruction is executing when an interrupt becomes active, the total number of CPU clock cycles before the ISR begins would be as follows:

(1 to 5 cycles for JMP to finish) + (13 cycles for interrupt routine) + (7 cycles for LJMP) = 21 to 25 cycles.

In the example above, at 24 MHz, 25 clock cycles take 1.042 μs.

Interrupt Registers

The Interrupt Registers are discussed it the following sections.

Interrupt Clear Register

The Interrupt Clear Registers (INT_CLRx) are used to enable the individual interrupt sources' ability to clear posted interrupts.

When an INT_CLRx register is read, any bits that are set indicates an interrupt has been posted for that hardware resource. Therefore, reading these registers gives the user the ability to determine all posted interrupts.

Table 69. Interrupt Clear 0 (INT_CLR0) [0xDA] [R/W]

Bit #	7	6	5	4	3	2	1	0
Field	GPIO Port 1	Sleep Timer	INT1	GPIO Port 0	SPI Receive	SPI Transmit	INT0	POR
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Default	0	0	0	0	0	0	0	0

When reading this register,
0 = There's no posted interrupt for the corresponding hardware
1 = Posted interrupt for the corresponding hardware present

Writing a '0' to the bits clears the posted interrupts for the corresponding hardware. Writing a '1' to the bits and to the ENSWINT (Bit 7 of the INT_MSK3 Register) posts the corresponding hardware interrupt

Table 70. Interrupt Clear 1 (INT_CLR1) [0xDB] [R/W]

Bit #	7	6	5	4	3	2	1	0
Field	Reserved	Prog Interval Timer	1 ms Timer	USB Active	USB Reset	USB EP2	USB EP1	USB EP0
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Default	0	0	0	0	0	0	0	0

When reading this register,

0 = There's no posted interrupt for the corresponding hardware

1 = Posted interrupt for the corresponding hardware present

Writing a '0' to the bits clears the posted interrupts for the corresponding hardware. Writing a '1' to the bits AND to the ENSWINT (Bit 7 of the INT_MSK3 Register) posts the corresponding hardware interrupt

Bit 7   Reserved

Table 71. Interrupt Clear 2 (INT_CLR2) [0xDC] [R/W]

Bit #	7	6	5	4	3	2	1	0
Field	Reserved	Reserved	Reserved	GPIO Port 2	Reserved	INT2	16-bit Counter Wrap	Reserved
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Default	0	0	0	0	0	0	0	0

When reading this register,

0 = There's no posted interrupt for the corresponding hardware

1 = Posted interrupt for the corresponding hardware present

Writing a '0' to the bits clears the posted interrupts for the corresponding hardware. Writing a '1' to the bits AND to the ENSWINT (Bit 7 of the INT_MSK3 Register) posts the corresponding hardware interrupt

Bits 7,6,5,3,0 Reserved

Interrupt Mask Registers

The Interrupt Mask Registers (INT_MSKx) are used to enable the individual interrupt sources' ability to create pending interrupts.

There are four Interrupt Mask Registers (INT_MSK0, INT_MSK1, INT_MSK2, and INT_MSK3), which may be referred to in general as INT_MSKx. If cleared, each bit in an INT_MSKx register prevents a posted interrupt from becoming a pending interrupt (input to the priority encoder). However, an interrupt can still post even if its mask bit is zero. All INT_MSKx bits are independent of all other INT_MSKx bits.

If an INT_MSKx bit is set, the interrupt source associated with that mask bit may generate an interrupt that becomes a pending interrupt.

The Enable Software Interrupt (ENSWINT) bit in INT_MSK3[7] determines the way an individual bit value written to an INT_CLRx register is interpreted. When is cleared, writing 1's to an INT_CLRx register has no effect. However, writing 0's to an INT_CLRx register, when ENSWINT is cleared, causes the corresponding interrupt to clear. If the ENSWINT bit is set, any 0's written to the INT_CLRx registers are ignored. However, 1's written to an INT_CLRx register, while ENSWINT is set, causes an interrupt to post for the corresponding interrupt.

Software interrupts can aid in debugging interrupt service routines by eliminating the need to create system level interactions that are sometimes necessary to create a hardware-only interrupt.

Table 72. Interrupt Mask 3 (INT_MSK3) [0xDE] [R/W]

Bit #	7	6	5	4	3	2	1	0
Field	ENSWINT	Reserved						
Read/Write	R/W	–	–	–	–	–	–	–
Default	0	0	0	0	0	0	0	0

Bit 7   Enable Software Interrupt (ENSWINT)

0 = Disable. Writing 0's to an INT_CLRx register, when ENSWINT is cleared, causes the corresponding interrupt to clear

1 = Enable. Writing 1's to an INT_CLRx register, when ENSWINT is set, causes the corresponding interrupt to post

Bits 6:0   Reserved

Interrupt Vector Clear Register

Table 76. Interrupt Vector Clear Register (INT_VC) [0xE2] [R/W]

Bit #	7	6	5	4	3	2	1	0
Field	Pending Interrupt [7:0]							
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Default	0	0	0	0	0	0	0	0

The Interrupt Vector Clear Register (INT_VC) holds the interrupt vector for the highest priority pending interrupt when read, and when written clears all pending interrupts

Bits 7:0   Pending Interrupt [7:0]
8-bit data value holds the interrupt vector for the highest priority pending interrupt. Writing to this register clears all pending interrupts

USB Transceiver

USB Transceiver Configuration

Table 77. USB Transceiver Configure Register (USBXCR) [0x74] [R/W]

Bit #	7	6	5	4	3	2	1	0
Field	USB Pull-up Enable	Reserved						USB Force State
Read/Write	R/W	–	–	–	–	–	–	R/W
Default	0	0	0	0	0	0	0	0

Bit 7   USB Pull-up Enable

0 = Disable the pull-up resistor on D–

1 = Enable the pull-up resistor on D–. This pull-up is to V_{CC}. This bit should be cleared in sleep mode.

Bits 6:1   Reserved

Bit 0   USB Force State

This bit allows the state of the USB I/O pins DP and D+ to be forced to a state while USB is enabled

0 = Disable USB Force State

1 = Enable USB Force State. Allows the D– and D+ pins to be controlled by P1.1 and P1.0 respectively when the USBIO is in USB mode. Refer to Table 46 for more information

Note The USB transceiver has a dedicated 3.3 V regulator for USB signalling purposes and to provide for the 1.5 K D– pull-up. Unlike the other 3.3 V regulator, this regulator cannot be controlled/accessed by firmware. When the device is suspended, this regulator is disabled along with the bandgap (which provides the reference voltage to the regulator) and the D– line is pulled up to 5 V through an alternate 6.5 K resistor. During wakeup following a suspend, the band gap and the regulator are switched on in any order. Under an extremely rare case when the device wakes up following a bus reset condition and the voltage regulator and the band gap turn on in that particular order, there is possibility of a glitch/low pulse occurring on the D– line. The host can misinterpret this as a deattach condition. This condition, although rare, can be avoided by keeping the bandgap circuitry enabled during sleep. This is achieved by setting the 'No Buzz' bit, bit[5] in the OSC_CR0 register. This is an issue only if the device is put to sleep during a bus reset condition

USB Serial Interface Engine (SIE)

The SIE allows the microcontroller to communicate with the USB host at low speed data rates (1.5 Mbps). The SIE simplifies the interface between the microcontroller and USB by incorporating hardware that handles the following USB bus activity independently of the microcontroller:

■ Translating the encoded received data and formatting the data to be transmitted on the bus

■ CRC checking and generation. Flagging the microcontroller if errors exist during transmission

■ Address checking. Ignoring the transactions not addressed to the device

■ Sending appropriate ACK/NAK/STALL handshakes

■ Identifying token type (SETUP, IN, or OUT). Setting the appropriate token bit after a valid token is received

■ Placing valid received data in the appropriate endpoint FIFOs

■ Sending and updating the data toggle bit (Data1/0)

■ Bit stuffing/unstuffing.

Firmware is required to handle the rest of the USB interface with the following tasks:

■ Coordinate enumeration by decoding USB device requests

■ Fill and empty the FIFOs

■ Suspend/Resume coordination

■ Verify and select Data toggle values

USB Device

Table 78. USB Device Address (USBCR) [0x40] [R/W]

Bit #	7	6	5	4	3	2	1	0
Field	USB Enable	Device Address[6:0]						
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Default	0	0	0	0	0	0	0	0

The content of this register is cleared when a USB Bus Reset condition occurs

Bit 7 USB Enable

This bit must be enabled by firmware before the serial interface engine (SIE) responds to USB traffic at the address specified in Device Address [6:0]. When this bit is cleared, the USB transceiver enters power-down state. User's firmware should clear this bit prior to entering sleep mode to save power

0 = Disable USB device address and put the USB transceiver into power-down state

1 = Enable USB device address and put the USB transceiver into normal operating mode

Bits 6:0 Device Address [6:0]

These bits must be set by firmware during the USB enumeration process (for example, SetAddress) to the non-zero address assigned by the USB host

Table 79. Endpoint 0, 1, and 2 Count (EP0CNT–EP2CNT) [0x41, 0x43, 0x45] [R/W]

Bit #	7	6	5	4	3	2	1	0
Field	Data Toggle	Data Valid	Reserved		Byte Count[3:0]			
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Default	0	0	0	0	0	0	0	0

Bit 7 Data Toggle

This bit selects the DATA packet's toggle state. For IN transactions, firmware must set this bit to the select the transmitted Data Toggle. For OUT or SETUP transactions, the hardware sets this bit to the state of the received Data Toggle bit.

0 = DATA0

1 = DATA1

Bit 6 Data Valid

This bit is used for OUT and SETUP tokens only. This bit is cleared to '0' if CRC, bitstuff, or PID errors have occurred. This bit does not update for some endpoint mode settings

0 = Data is invalid. If enabled, the endpoint interrupt occurs even if invalid data is received

1 = Data is valid

Bits 5:4 Reserved

Bits 3:0 Byte Count Bit [3:0]

Byte Count Bits indicate the number of data bytes in a transaction: For IN transactions, firmware loads the count with the number of bytes to be transmitted to the host from the endpoint FIFO. Valid values are 0 to 8 inclusive. For OUT or SETUP transactions, the count is updated by hardware to the number of data bytes received, plus 2 for the CRC bytes. Valid values are 2–10 inclusive.

For Endpoint 0 Count Register, whenever the count updates from a SETUP or OUT transaction, the count register locks and cannot be written by the CPU. Reading the register unlocks it. This prevents firmware from overwriting a status update on it

Endpoint 0 Mode

Because both firmware and the SIE are allowed to write to the Endpoint 0 Mode and Count Registers the SIE provides an interlocking mechanism to prevent accidental overwriting of data.

When the SIE writes to these registers they are locked and the processor cannot write to them until after it has read them. Writing to this register clears the upper four bits regardless of the value written.

Table 80. Endpoint 0 Mode (EP0MODE) [0x44] [R/W]

Bit #	7	6	5	4	3	2	1	0
Field	Setup Received	IN Received	OUT Re-ceived	ACK'd Trans	Mode[3:0]			
Read/Write	R/C[3]	R/C[3]	R/C[3]	R/C[3]	R/W	R/W	R/W	R/W
Default	0	0	0	0	0	0	0	0

Bit 7   SETUP Received
This bit is set by hardware when a valid SETUP packet is received. It is forced HIGH from the start of the data packet phase of the SETUP transactions until the end of the data phase of a control write transfer and cannot be cleared during this interval. While this bit is set to '1', the CPU cannot write to the EP0 FIFO. This prevents firmware from overwriting an incoming SETUP transaction before firmware has a chance to read the SETUP data
This bit is cleared by any non-locked writes to the register
0 = No SETUP received
1 = SETUP received

Bit 6   IN Received
This bit, when set, indicates a valid IN packet has been received. This bit is updated to '1' after the host acknowl-edges an IN data packet.When clear, it indicates that either no IN has been received or that the host didn't acknowledge the IN data by sending an ACK handshake
This bit is cleared by any non-locked writes to the register.
0 = No IN received
1 = IN received

Bit 5   OUT Received
This bit, when set, indicates a valid OUT packet has been received and ACKed. This bit is updated to '1' after the last received packet in an OUT transaction. When clear, it indicates no OUT received
This bit is cleared by any non-locked writes to the register
0 = No OUT received
1 = OUT received

Bit 4   ACK'd Transaction
The ACK'd transaction bit is set whenever the SIE engages in a transaction to the register's endpoint that com-pletes with a ACK packet
This bit is cleared by any non-locked writes to the register
1 = The transaction completes with an ACK
0 = The transaction does not complete with an ACK

Bits 3:0   Mode [3:0]
The endpoint modes determine how the SIE responds to USB traffic that the host sends to the endpoint. The mode controls how the USB SIE responds to traffic and how the USB SIE changes the mode of that endpoint as a result of host packets to the endpoint

Table 81. Endpoint 1 and 2 Mode (EP1MODE – EP2MODE) [0x45, 0x46] [R/W]

Bit #	7	6	5	4	3	2	1	0
Field	Stall	Reserved	NAK Int Enable	ACK'd Transaction	Mode[3:0]			
Read/Write	R/W	R/W	R/W	R/C (Note 3)	R/W	R/W	R/W	R/W
Default	0	0	0	0	0	0	0	0

Bit 7   Stall
When this bit is set the SIE stalls an OUT packet if the Mode Bits are set to ACK-OUT, and the SIE stalls an IN packet if the mode bits are set to ACK-IN. This bit must be clear for all other modes

Bit 6   Reserved

Bit 5   NAK Int Enable
This bit, when set, causes an endpoint interrupt to be generated even when a transfer completes with a NAK. Unlike enCoRe, CYRF69313 family members do not generate an endpoint interrupt under these conditions unless this bit is set
0 = Disable interrupt on NAK'd transactions
1 = Enable interrupt on NAK'd transaction

Bit 4   ACK'd Transaction
The ACK'd transaction bit is set whenever the SIE engages in a transaction to the register's endpoint that completes with an ACK packet
This bit is cleared by any writes to the register
0 = The transaction does not complete with an ACK
1 = The transaction completes with an ACK

Bits 3:0   Mode [3:0]
The endpoint modes determine how the SIE responds to USB traffic that the host sends to the endpoint. The mode controls how the USB SIE responds to traffic and how the USB SIE changes the mode of that endpoint as a result of host packets to the endpoint.

Note: When the SIE writes to the EP1MODE or the EP2MODE register it blocks firmware writes to the EP2MODE or the EP1MODE registers, respectively (if both writes occur in the same clock cycle). This is because the design employs only one common 'update' signal for both EP1MODE and EP2MODE registers. Thus, when SIE writes to the EP1MODE register, the update signal is set and this prevents firmware writes to EP2MODE register. SIE writes to the endpoint mode registers have higher priority than firmware writes. This mode register write block situation can put the endpoints in incorrect modes. Firmware must read the EP1/2MODE registers immediately following a firmware write and rewrite if the value read is incorrect

Endpoint Data Buffers

The three data buffers are used to hold data for both IN and OUT transactions. Each data buffer is 8 bytes long. The reset values of the Endpoint Data Registers are unknown. Unlike past enCoRe parts the USB data buffers are only accessible in the I/O space of the processor.

Table 82. Endpoint 0 Data (EP0DATA) [0x50-0x57] [R/W]

Bit #	7	6	5	4	3	2	1	0
Field	Endpoint 0 Data Buffer [7:0]							
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Default	Unknown	Unknown	Unknown	Unknown	Unknown	Unknown	Unknown	Unknown

The Endpoint 0 buffer is comprised of 8 bytes located at address 0x50 to 0x57

Table 83. Endpoint 1 Data (EP1DATA) [0x58-0x5F] [R/W]

Bit #	7	6	5	4	3	2	1	0
Field	Endpoint 1 Data Buffer [7:0]							
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Default	Unknown	Unknown	Unknown	Unknown	Unknown	Unknown	Unknown	Unknown

The Endpoint 1buffer is comprised of 8 bytes located at address 0x58 to 0x5F

Table 84. Endpoint 2 Data (EP2DATA) [0x60-0x67] [R/W]

Bit #	7	6	5	4	3	2	1	0
Field	Endpoint 2 Data Buffer [7:0]							
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Default	Unknown	Unknown	Unknown	Unknown	Unknown	Unknown	Unknown	Unknown

The Endpoint 2 buffer is comprised of 8 bytes located at address 0x60 to 0x67

USB Mode Tables

Mode	Encoding	SETUP	IN	OUT	Comments
DISABLE	0000	Ignore	Ignore	Ignore	Ignore all USB traffic to this endpoint. Used by Data and Control endpoints
NAK IN/OUT	0001	Accept	NAK	NAK	NAK IN and OUT token. Control endpoint only
STATUS OUT ONLY	0010	Accept	STALL	Check	STALL IN and ACK zero byte OUT. Control endpoint only
STALL IN/OUT	0011	Accept	STALL	STALL	STALL IN and OUT token. Control endpoint only
STATUS IN ONLY	0110	Accept	TX0 byte	STALL	STALL OUT and send zero byte data for IN token. Control endpoint only
ACK OUT – STATUS IN	1011	Accept	TX0 byte	ACK	ACK the OUT token or send zero byte data for IN token. Control endpoint only
ACK IN – STATUS OUT	1111	Accept	TX Count	Check	Respond to IN data or Status OUT. Control endpoint only
NAK OUT	1000	Ignore	Ignore	NAK	Send NAK handshake to OUT token. Data endpoint only
ACK OUT (STALL = 0)	1001	Ignore	Ignore	ACK	This mode is changed by the SIE to mode 1000 on issuance of ACK handshake to an OUT. Data endpoint only
ACK OUT (STALL = 1)	1001	Ignore	Ignore	STALL	STALL the OUT transfer
NAK IN	1100	Ignore	NAK	Ignore	Send NAK handshake for IN token. Data endpoint only
ACK IN (STALL = 0)	1101	Ignore	TX Count	Ignore	This mode is changed by the SIE to mode 1100 after receiving ACK handshake to an IN data. Data endpoint only
ACK IN (STALL = 1)	1101	Ignore	STALL	Ignore	STALL the IN transfer. Data endpoint only
Reserved	0101	Ignore	Ignore	Ignore	These modes are not supported by SIE. Firmware should not use this mode in Control and Data endpoints
Reserved	0111	Ignore	Ignore	Ignore	
Reserved	1010	Ignore	Ignore	Ignore	
Reserved	0100	Ignore	Ignore	Ignore	
Reserved	1110	Ignore	Ignore	Ignore	

Mode Column

The 'Mode' column contains the mnemonic names given to the modes of the endpoint. The mode of the endpoint is determined by the four-bit binaries in the 'Encoding' column as discussed in the following section. The Status IN and Status OUT represent the status IN or OUT stage of the control transfer.

Encoding Column

The contents of the 'Encoding' column represent the Mode Bits [3:0] of the Endpoint Mode Registers (Table 80 and Table 81). The endpoint modes determine how the SIE responds to different tokens that the host sends to the endpoints. For example, if the Mode Bits [3:0] of the Endpoint 0 Mode Register are set to '0001', which is NAK IN/OUT mode, the SIE sends an ACK handshake in response to SETUP tokens and NAK any IN or OUT tokens.

SETUP, IN, and OUT Columns

Depending on the mode specified in the 'Encoding' column, the 'SETUP', 'IN', and 'OUT' columns contain the SIE's responses when the endpoint receives SETUP, IN, and OUT tokens, respectively.

A 'Check' in the Out column means that upon receiving an OUT token the SIE checks to see whether the OUT is of zero length and has a Data Toggle (Data1/0) of 1. If these conditions are true, the SIE responds with an ACK. If any of the above conditions is not met, the SIE responds with either a STALL or Ignore.

A 'TX Count' entry in the IN column means that the SIE transmits the number of bytes specified in the Byte Count Bit [3:0] of the Endpoint Count Register (Table 79) in response to any IN token.

Details of Mode for Differing Traffic Conditions

SIE Mode	Token	Bus Event Count	Dval	D0/1	SIE Response	S	I	O	A	MODE	DTOG	DVAL	COUNT	EP0 FIFO	Interrupt	Comments

Radio Function Register Descriptions

All registers are read and writeable, except where noted. Registers may be written to or read from either individually or in sequential groups. A single-byte read or write reads or writes from the addressed register. Incrementing burst read and write is a sequence that begins with an address, and then reads or writes to/from each register in address order for as long as clocking continues. It is possible to repeatedly read (poll) a single register using a non-incrementing burst read. These registers are managed and configured over SPI by the user firmware running in the microcontroller function.

Notes
4. b = read/write; r = read only; w = write only; '-' = not used, default value is undefined.
5. SOP_CODE_ADR default = 0x17FF9E213690C782.
6. DATA_CODE_ADR default = 0x02F9939702FA5CE3012BF1DB0132BE6F.
7. PREAMBLE_ADR default = 0x333302
8. Registers must be configured or accessed only when the radio is in IDLE or SLEEP mode.The GPIOs,RSSI registers can be accessed in Active Tx and Rx mode.
9. EOP_CTRL_ADR[6:4] should never have the value of "000" i.e. EOP Hint Symbol count should never be "0".

Absolute Maximum Ratings

Exceeding maximum ratings may shorten the useful life of the device. User guidelines are not tested.

Storage Temperature .... −40 °C to +90 °C

Ambient Temperature with Power Applied...... 0 °C to +70 °C

Supply Voltage on any power supply
pin relative to V_{SS} ....−0.3 V to +3.9 V

DC Voltage to Logic Inputs[10] .... −0.3 V to V_{IO} +0.3 V

DC Voltage applied to Outputs
in High Z State .... −0.3 V to V_{IO} +0.3 V

Static Discharge Voltage (Digital)[11] .... >2000 V

Static Discharge Voltage (RF)[11] .... 1100 V

Latch up Current.....................................+200 mA, −200 mA

Ground Voltage... 0 V

F_{OSC} (Crystal Frequency)........................... 12 MHz ±30 ppm

DC Characteristics (T = 25 °C)

Parameter	Description	Conditions	Min	Typ	Max	Unit
Radio Function Operating Voltages (For RF activity, $V_{cc} = V_{bat}$ = 3.0 V to 3.6 V)						
V_{BAT}	Battery voltage	0 °C – 70 °C	2.7	–	3.6	V
V_{IO}	V_{IO} Voltage		2.7	–	3.6	V
V_{CC}	V_{CC} Voltage	0 °C – 70 °C	2.7	–	3.6	V
MCU Function Operating Voltages						
V_{DD_MICRO1}	Operating voltage	No USB activity, CPU speed $\leq$ 12 MHz	4.0	–	5.25	V
V_{DD_MICRO2}	Operating voltage	USB activity, CPU speed $\leq$ 12 MHz. Flash programming	4.35	–	5.25	V
Device Current (For total current consumption in different modes, for example Radio, active, MCU, sleep, etc., add Radio Function Current and MCU Function Current)						
I_{DD} (GFSK)[12]	Average I_{DD}, 1 Mbps, slow channel	PA = 5, 2-way, 4 bytes/10 ms	–	10.87	–	mA
I_{DD} (32-8DR)[12]	Average I_{DD}, 250 kbps, fast channel	PA = 5, 2-way, 4 bytes/10 ms	–	11.2	–	mA
I_{SB}	Sleep Mode I_{DD}	Radio function and MCU function in Sleep mode	–	40.1	–	µA
Radio Function Current (V_{DD_Micro} = 5.0 V, MCU sleep)						
IDLE I_{CC}	Radio Off, XTAL Active	XOUT disabled	–	2.1	–	mA
I_{synth}	I_{CC} during Synth Start		–	9.8	–	mA
TX I_{CC}	I_{CC} during transmit	PA = 5 (–5 dBm)	–	22.4	–	mA
TX I_{CC}	I_{CC} during transmit	PA = 6 (0 dBm)	–	27.7	–	mA
RX I_{CC}	I_{CC} during receive	LNA off, ATT on	–	20.2	–	mA
RX I_{CC}	I_{CC} during receive	LNA on, ATT off	–	23.4	–	mA
MCU Function Current (V_{DD_Micro} = 5.0 V)						
I_{DD_MICRO1}	V_{DD_MICRO} operating supply current	No GPIO loading, 6 MHz	–	10	–	mA
I_{SB1}	Standby current	Internal Oscillators, Bandgap, Flash, CPU Clock, Timer Clock, USB Clock all disabled	–	4	10	µA
USB Interface						
V_{ON}	Static output High	15 K ± 5% Ohm to V_{SS}	2.8	–	3.6	V
V_{OFF}	Static output Low	R_{UP} is enabled	–	–	0.3	V
V_{DI}	Differential input sensitivity		0.2	–	–	V
V_{CM}	Differential input common mode range		0.8	–	2.5	V

Notes
10. It is permissible to connect voltages above V_{IO} to inputs through a series resistor limiting input current to 1 mA. AC timing not guaranteed.
11. Human Body Model (HBM).
12. Includes current drawn while starting crystal, starting synthesizer, transmitting packet (including SOP and CRC16), changing to receive mode, and receiving ACK handshake. Device is in sleep except during this transaction.

DC Characteristics (T = 25 °C) (continued)

Parameter	Description	Conditions	Min	Typ	Max	Unit
V_{SE}	Single ended receiver threshold		0.8	–	2	V
C_{IN}	Transceiver capacitance		–	–	20	pF
I_{IO}	Hi-Z State data line leakage	$0\ V < V_{IN} < 3.3\ V$	–10	–	10	µA
Radio Function GPIO Interface						
V_{OH1}	Output High voltage condition 1	At $I_{OH} = -100.0\ µA$	$V_{IO} - 0.1$	V_{IO}	–	V
V_{OH2}	Output High voltage condition 2	At $I_{OH} = -2.0\ mA$	$V_{IO} - 0.4$	V_{IO}	–	V
V_{OL}	Output Low voltage	At $I_{OL} = 2.0\ mA$	–	0	0.4	V
V_{IH}	Input High voltage		$0.76\ V_{IO}$	–	V_{IO}	V
V_{IL}	Input Low voltage		0	–	$0.24\ V_{IO}$	V
I_{IL}	Input leakage current	$0 < V_{IN} < V_{IO}$	–1	0.26	+1	µA
C_{IN}	Pin Input capacitance	except XTAL, RF_N, RF_P, RF_{BIAS}	–	3.5	10	pF
MCU Function GPIO Interface						
R_{UP}	Pull-up resistance		4	–	12	KΩ
V_{ICR}	Input threshold voltage Low, CMOS mode	Low to High edge	40%	–	65%	V_{CC}
V_{ICF}	Input threshold voltage Low, CMOS mode	High to Low edge	30%	–	55%	V_{CC}
V_{HC}	Input hysteresis voltage, CMOS mode	High to Low edge	3%	–	10%	V_{CC}
V_{ILTTL}	Input Low voltage, TTL mode	IO-pin Supply = 2.9–3.6 V	–	–	0.8	V
V_{IHTTL}	Input High voltage, TTL mode	IO-pin Supply = 4.0–5.5 V	2.0	–	–	V
V_{OL1}	Output Low voltage, High drive[13]	$I_{OL1} = 50\ mA$	–	–	0.8	V
V_{OL2}	Output Low voltage, High drive[13]	$I_{OL1} = 25\ mA$	–	–	0.4	V
V_{OL3}	Output Low voltage, Low drive[13]	$I_{OL2} = 8\ mA$	–	–	0.4	V
V_{OH}	Output High voltage[13]	$I_{OH} = 2\ mA$	$V_{CC} - 0.5$	–	–	V

Note
13. Except for pins P1.0, P1.1 in GPIO mode.

RF Characteristics

Table 86. Radio Parameters

Parameter Description	Conditions	Min	Typ	Max	Unit
RF Frequency Range	Subject to regulations.	2.400	–	2.497	GHz
Receiver (T = 25 °C, V_{CC} = V_{bat} = 3.0 V, f_{OSC} = 12.000 MHz, BER < 10^{-3})					
Sensitivity 250 kbps 32-8DR	BER 1E-3	–	–90	–	dBm
Sensitivity GFSK	BER 1E-3, ALL SLOW = 1	–	–84	–	dBm
LNA gain		–	22.8	–	dB
ATT gain		–	–31.7	–	dB
Maximum received signal	LNA On	–15	–6	–	dBm
RSSI value for PWR_{in} –60 dBm	LNA On	–	21	–	Count
RSSI slope		–	1.9	–	dB/Count
Interference Performance (CER 1E-3)					
Co-channel Interference rejection Carrier-to-Interference (C/I)	C = –60 dBm,	v	9	–	dB
Adjacent (±1 MHz) channel selectivity C/I 1 MHz	C = –60 dBm	–	3	–	dB
Adjacent (±2 MHz) channel selectivity C/I 2 MHz	C = –60 dBm	–	–30	–	dB
Adjacent ($\geq$ 3 MHz) channel selectivity C/I $\geq$ 3 MHz	C = –67 dBm	–	–38	–	dB
Out-of-Band Blocking 30 MHz–12.75 MHz[14]	C = –67 dBm	–	–30	–	dBm
Intermodulation	C = –64 dBm, Δf = 5,10 MHz	–	–36	–	dBm
Receive Spurious Emission					
800 MHz	100 kHz ResBW	–	–79	–	dBm
1.6 GHz	100 kHz ResBW	–	–71	–	dBm
3.2 GHz	100 kHz ResBW	–	–65	–	dBm
Transmitter (T = 25 °C, V_{CC} = V_{bat} =3.0 V, f_{OSC} = 12.000 MHz)					
Maximum RF transmit power	PA = 6	–2	0	+2	dBm
Maximum RF transmit power	PA = 5	–7	–5	–3	dBm
Maximum RF transmit power	PA = 0	–	–35	–	dBm
RF power control range		–	39	–	dB
RF power range control step size	Six steps, monotonic	–	5.6	–	dB
Frequency deviation Min	PN Code Pattern 10101010	–	270	–	kHz
Frequency deviation Max	PN Code Pattern 11110000	–	323	–	kHz
Error vector magnitude (FSK error)	>0 dBm	–	10	–	%rms
Occupied bandwidth	–6 dBc, 100 kHz ResBW	500	876	–	kHz
Transmit Spurious Emission (PA = 6)					
In-band spurious second channel power (±2 MHz)		–	–38	–	dBm
In-band spurious third channel power ($\geq$3 MHz)		–	–44	–	dBm
Non-harmonically related spurs (8.000 GHz)		–	–38	–	dBm
Non-harmonically related spurs (1.6 GHz)		–	–34	–	dBm
Non-harmonically related spurs (3.2 GHz)		–	–47	–	dBm
Harmonic spurs (Second Harmonic)		–	–43	–	dBm
Harmonic spurs (Third Harmonic)		–	–48	–	dBm

Notes
14. Exceptions F/3 and 5C/3.

Table 86. Radio Parameters (continued)

Parameter Description	Conditions	Min	Typ	Max	Unit
Fourth and Greater Harmonics		–	–59	–	dBm
Power Management (Crystal PN# eCERA GF-1200008)					
Crystal start to 10 ppm		–	0.7	1.3	ms
Crystal start to IRQ	XSIRQ EN = 1	–	0.6		ms
Synth Settle	Slow channels	–	–	270	µs
Synth Settle	Medium channels	–	–	180	µs
Synth Settle	Fast channels	–	–	100	µs
Link turnaround time	GFSK	–	–	30	µs
Link turnaround time	250 kbps	–	–	62	µs
Max packet length	< 60 ppm crystal-to-crystal	–	–	40	bytes

AC Test Loads and Waveforms for Digital Pins

Figure 18. AC Test Loads and Waveforms for Digital Pins
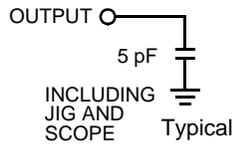

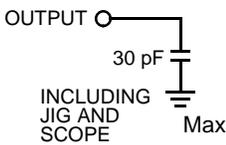

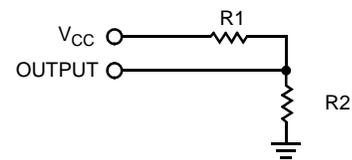

Parameter		Unit
R1	1071	Ω
R2	937	Ω
R_{TH}	500	Ω
V_{TH}	1.4	V
V_{CC}	3.00	V
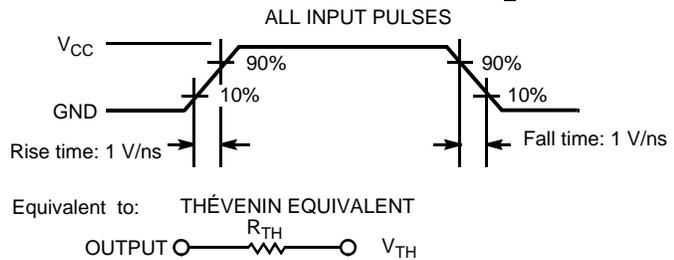

AC Characteristics

Parameter	Description	Conditions	Min	Typical	Max	Unit
Clock						
F_{IMO}	Internal main oscillator frequency	No USB present With USB present	22.8 23.64	– 	25.2 24.36	MHz MHz
F_{ILO}	Internal low-power oscillator	Normal Mode Low Power Mode	29.44 35.84	– 	37.12 47.36	KHz KHz
3.3 V Regulator						
V_{ORIP}	Output ripple voltage		45	–	55	%
USB Driver						
T_{R1}	Transition rise time	C_{LOAD} = 200 pF	75	–	–	ns
T_{R2}	Transition rise time	C_{LOAD} = 600 pF	–	–	300	ns
T_{F1}	Transition fall time	C_{LOAD} = 200 pF	75	–	–	ns
T_{F2}	Transition fall time	C_{LOAD} = 600 pF	–	–	300	ns
T_R	Rise/Fall time matching		80	–	125	%
V_{CRS}	Output signal crossover voltage		1.3	–	2.0	V
USB Data Timing						
T_{DRATE}	Low speed data rate	Ave. Bit Rate (1.5 Mbps ± 1.5%)	1.4775	–	1.5225	Mbps
T_{DJR1}	Receiver data jitter tolerance	To next transition	–75	–	75	ns
T_{DJR2}	Receiver data jitter tolerance	To pair transition	–45	–	45	ns
T_{DEOP}	Differential to EOP transition skew		–40	–	100	ns
T_{EOPR1}	EOP width at receiver	Rejects as EOP	–	–	330	ns
T_{EOPR2}	EOP width at receiver	Accept as EOP	675	–	–	ns
T_{EOPT}	Source EOP width		1.25	–	1.5	μs
T_{UDJ1}	Differential driver jitter	To next transition	–95	–	95	ns
T_{UDJ2}	Differential driver jitter	To pair transition	–95	–	95	ns
T_{LST}	Width of SE0 during different transition		–	–	210	ns
Non-USB Mode Driver Characteristics						
T_{FPS2}	SDATA/SCK transition fall time		50	–	300	ns
SPI Timing						
T_{SMCK}	SPI master clock rate	F_{CPUCLK}/6	–	–	2	MHz
T_{SSCK}	SPI slave clock rate		–	–	2.2	MHz
T_{SCKH}	SPI clock high time	High for CPOL = 0, Low for CPOL = 1	125	–	–	ns
T_{SCKL}	SPI clock low time	Low for CPOL = 0, High for CPOL = 1	125	–	–	ns
T_{MDO}	Master data output time[15]	SCK to data valid	–25	–	50	ns
T_{MDO1}	Master data output time, First bit with CPHA = 0	Time before leading SCK edge	100	–	–	ns
T_{MSU}	Master input data setup time		50	–	–	ns
T_{MHD}	Master input data hold time		50	–	–	ns
T_{SSU}	Slave input data setup time		50	–	–	ns
T_{SHD}	Slave input data hold time		50	–	–	ns
T_{SDO}	Slave data output time	SCK to data valid	–	–	100	ns
T_{SDO1}	Slave data output time, First bit with CPHA = 0	Time after SS LOW to data valid	–	–	100	ns
T_{SSS}	Slave select setup time	Before first SCK edge	150	–	–	ns
T_{SSH}	Slave select hold time	After last SCK edge	150	–	–	ns

Note
15. In Master mode first bit is available 0.5 SPICLK cycle before Master clock edge available on the SCLK pin.

Commercial

X = Pb-free

40-pin QFN package
F = Punch, T = Sawn

Part number

Marketing code: RF =
Wireless (radio frequency)
product line

Company ID: CY = Cypress
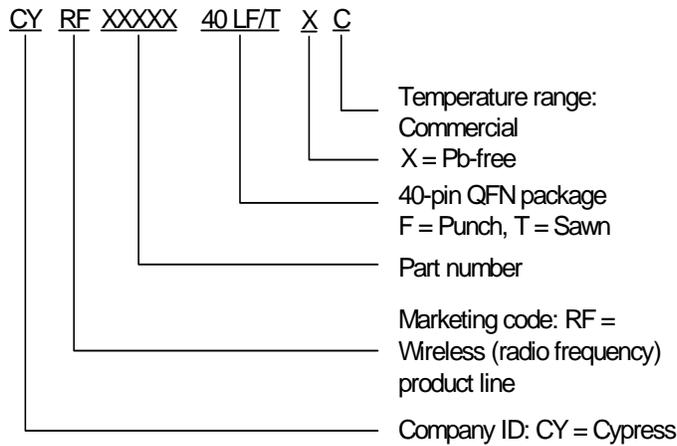

Package Handling

Some IC packages require baking before they are soldered onto a PCB to remove moisture that may have been absorbed after leaving the factory. A label on the packaging has details about actual bake temperature and the minimum bake time to remove this moisture.The maximum bake time is the aggregate time that the parts are exposed to the bake temperature. Exceeding this exposure time may degrade device reliability.

Table 87. Package Handling

Parameter	Description	Min	Typ	Max	Unit
T$_{BAKETEMP}$	Bake Temperature		125	see package label	°C
t$_{BAKETIME}$	Bake Time	see package label		24	hours

Acronyms

Table 88. Acronyms Used in this Document

Acronym	Description
ACK	Acknowledge (packet received, no errors)
BER	Bit error rate
BOM	Bill of materials
CMOS	complementary metal oxide semiconductor
CRC	cyclic redundancy check
FEC	forward error correction
FER	frame error rate
GFSK	Gaussian frequency-shift keying
HBM	Human body model
ISM	Industrial, scientific, and medical
IRQ	interrupt request
MCU	microcontroller unit
NRZ	non return to zero
PLL	phase-locked loop
QFN	Quad flat no-leads
RSSI	received signal strength indication
RF	radio frequency
Rx	receive
Tx	transmit

Document Conventions

Units of Measure

Table 89. Units of Measure

Symbol	Unit of Measure
°C	degree Celsius
dB	decibels
dBc	decibel relative to carrier
dBm	decibel-milliwatt
Hz	hertz
KB	1024 bytes
Kbit	1024 bits
kHz	kilohertz
kΩ	kilohm
MHz	megahertz
MΩ	megaohm
μA	microampere
μs	microsecond
μV	microvolt
μVrms	microvolts root-mean-square
μW	microwatts
mA	milliampere
ms	millisecond
mV	millivolt
nA	nanoampere
ns	nanosecond
nV	nanovolt
Ω	ohm
pp	peak-to-peak
ppm	parts per million
ps	picosecond
sps	samples per second
V	volt
